Geometry with Trigonometry

2nd Edition

Patrick D. Barry
Professor Emeritus of Mathematics,
School of Mathematical Sciences,
University College, Cork.

“All things stand by proportion.”
George Puttenham (1529–1590)

“Mathematics possesses not only truth, but supreme beauty – a beauty cold and austere like that of sculpture, and capable of stern perfection, such as only great art can show.”
To my late wife Fran, my children Conor, Una and Brian, and my several grandchildren

About the author ..................................... xv
Preface ............................................. xvii
Glossary ........................................... xix

1 Preliminaries ........................................ 1
1.1 Historical note ..................................... 1
1.2 Note on deductive reasoning ..................... 3
1.2.1 Definitions ..................................... 3
1.2.2 Proof ......................................... 3
1.3 Euclid’s *The Elements* ............................ 4
1.3.1 ............................................. 4
1.3.2 Definitions ..................................... 4
1.3.3 Postulates and common notions ............... 6
1.3.4 ............................................. 7
1.3.5 Congruence .................................... 7
1.3.6 Quantities or magnitudes ..................... 8
1.4 Our approach ..................................... 9
1.4.1 Type of course ................................ 9
1.4.2 Need for preparation .......................... 9
1.5 Revision of geometrical concepts ............... 10
1.5.1 ............................................. 10
1.5.2 The basic shapes ................................ 10
1.5.3 Distance; degree-measure of an angle ........ 15
1.5.4 Our treatment of congruence .................. 17
1.5.5 Parallel lines ................................ 18
1.6 Pre-requisites .................................... 19
1.6.1 Set notation .................................. 19
1.6.2 Classical algebra ............................. 20
1.6.3 Other algebra ................................ 20
1.6.4 Distinctive property of real numbers among fields .. 20

2 Basic shapes of geometry ........................... 21
2.1 Lines, segments and half-lines .................... 21
2.1.1 Plane, points, lines ......................... 21
2.1.2 Natural order on a line ....................... 22
2.1.3 Reciprocal orders ............................ 23
2.1.4 Segments ..................................... 23
2.1.5 Half-lines .................................... 25
2.2 Open and closed half-planes ...................... 26
2.2.1 Convex sets .................................. 26
2.2.2 Open half-planes ............................. 26
2.2.3 Closed half-planes ........................... 27
2.3 Angle-supports, interior and exterior regions, angles .. 28
2.3.1 Angle-supports, interior regions ........................................ 28
2.3.2 Exterior regions ......................................................... 30
2.3.3 Angles ................................................................. 30
2.4 Triangles and convex quadrilaterals ..................................... 30
2.4.1 Terminology ........................................................... 30
2.4.2 Triangles ............................................................... 31
2.4.3 Pasch’s property, 1882 ............................................... 32
2.4.4 Convex quadrilaterals .................................................. 32

3 Distance; degree-measure of an angle ........................................ 35
3.1 Distance ........................................................................ 35
3.1.1 Axiom for distance ..................................................... 35
3.1.2 Derived properties of distance ....................................... 36
3.2 Mid-points ..................................................................... 38
3.2.1 ........................................................................... 38
3.3 A ratio result ................................................................... 39
3.3.1 ........................................................................... 39
3.4 The cross-bar theorem ....................................................... 40
3.4.1 ........................................................................... 40
3.5 Degree-measure of angles .................................................. 40
3.5.1 Axiom for degree-measure ........................................... 40
3.5.2 Derived properties of degree-measure ............................ 41
3.6 Mid-line of an angle-support ............................................. 44
3.6.1 Right-angles ............................................................ 44
3.6.2 Perpendicular lines ..................................................... 44
3.6.3 Mid-lines ................................................................ 45
3.7 Degree-measure of reflex angles ........................................ 46
3.7.1 ........................................................................... 46

4 Congruence of triangles; parallel lines ........................................ 49
4.1 Principles of congruence ..................................................... 49
4.1.1 Congruence of triangles ................................................. 49
4.2 Alternate angles, parallel lines ............................................ 53
4.2.1 Alternate angles ........................................................ 53
4.2.2 Parallel lines ............................................................ 54
4.3 Properties of triangles and half-planes ................................. 55
4.3.1 Side-angle relationships; the triangle inequality ................ 55
4.3.2 Properties of parallelism ................................................. 56
4.3.3 Dropping a perpendicular ............................................. 56
4.3.4 Projection and axial symmetry ...................................... 57
5 The parallel axiom; Euclidean geometry 61
5.1 The parallel axiom .......................... 61
5.1.1 Uniqueness of a parallel line ............... 61
5.2 Parallelograms ............................ 62
5.2.1 Parallelograms and rectangles ............... 62
5.2.2 Sum of measures of wedge-angles of a triangle 63
5.3 Ratio results for triangles .................... 64
5.3.1 Lines parallel to one side-line of a triangle 64
5.3.2 Similar triangles .......................... 67
5.4 Pythagoras’ theorem, c. 550B.C. ............... 69
5.5 Mid-lines and triangles ....................... 70
5.5.1 Harmonic ranges .......................... 70
5.6 Area of triangles, and convex quadrilaterals and polygons 72
5.6.1 Area of a triangle .......................... 72
5.6.2 Area of a convex quadrilateral ............... 75
5.6.3 Area of a convex polygon ................... 75

6 Cartesian coordinates; applications 81
6.1 Frame of reference, Cartesian coordinates .......... 81
6.1.1 ........................................ 81
6.2 Algebraic note on linear equations .................. 85
6.2.1 ........................................ 85
6.3 Cartesian equation of a line ........................ 86
6.3.1 ........................................ 86
6.4 Parametric equations of a line ....................... 89
6.4.1 ........................................ 89
6.5 Perpendicularity and parallelism of lines .......... 92
6.5.1 ........................................ 92
6.6 Projection and axial symmetry ...................... 93
6.6.1 ........................................ 93
6.6.2 Formula for area of a triangle .................. 94
6.6.3 Inequalities for closed half-planes ............... 95
6.7 Coordinate treatment of harmonic ranges .......... 95
6.7.1 New parametrisation of a line ................. 95
6.7.2 Interchange of pairs of points .................. 97
6.7.3 Distances from mid-point ...................... 98
6.7.4 Distances from end-point ..................... 98
6.7.5 Construction for a harmonic range ............... 99

7 Circles; their basic properties 103
7.1 Intersection of a line and a circle .................. 103
7.1.1 ........................................ 103
7.2 Properties of circles ........................... 105

## Contents

9.5.3 .............................................. 142
9.5.4 The Steiner-Lehmus theorem, 1842 .............. 142
9.6 Cosine and sine of angles equal in magnitude ....... 143
9.6.1 .............................................. 143

### 10 Complex coordinates; sensed angles; angles between lines  145

10.1 Complex coordinates .................................. 145
10.1.1 .............................................. 145
10.2 Complex-valued distance ............................. 148
10.2.1 Complex-valued distance ......................... 148
10.2.2 A complex-valued trigonometric function ......... 148
10.3 Rotations and axial symmetries .................... 150
10.3.1 Rotations .................................... 150
10.3.2 Formula for an axial symmetry ................. 151
10.4 Sensed angles ..................................... 153
10.4.1 .............................................. 153
10.5 Sensed-area ....................................... 156
10.5.1 .............................................. 156
10.5.2 Sensed-area of a triangle ......................... 156
10.5.3 A basic feature of sensed-area ................. 157
10.5.4 An identity for sensed-area ..................... 157
10.6 Isometries as compositions .......................... 158
10.6.1 .............................................. 158
10.7 Orientation of a triple of non-collinear points .... 160
10.7.1 .............................................. 160
10.8 Sensed angles of triangles, the sine rule .......... 162
10.8.1 .............................................. 162
10.9 Some results on circles ............................. 164
10.9.1 A necessary condition to lie on a circle ....... 164
10.9.2 A sufficient condition to lie on a circle ...... 165
10.9.3 Complex cross-ratio .................................. 165
10.9.4 Ptolemy’s theorem, c. 200A.D. ................. 166
10.10 Angles between lines .................................. 168
10.10.1 Motivation .................................... 168
10.10.2 Duo-sectors ................................... 168
10.10.3 Duo-angles .................................... 169
10.10.4 Duo-angles in standard position ............... 169
10.10.5 Addition of duo-angles in standard position .... 171
10.10.6 Addition formulae for tangents of duo-angles .... 173
10.10.7 Associativity of addition of duo-angles ......... 174
10.10.8 Group properties of duo-angles; sensed duo-angles ... 175
10.10.9 An application .................................. 176
10.11 A case of Pascal’s theorem, 1640 ................. 176
10.11.1 .............................................. 176
11 Vector and complex-number methods

11.1 Equipollence ........................................... 185
11.1.1 .................................................. 185
11.2 Sum of couples, multiplication of a couple by a scalar ............... 187
11.2.1 .................................................. 187
11.2.2 Vector space over \( \mathbb{R} \) ................................ 188
11.3 Scalar or dot products .................................. 190
11.3.1 .................................................. 190
11.4 Components of a vector .................................. 192
11.4.1 Components ........................................ 192
11.4.2 Areal coordinates ................................... 193
11.4.3 Cartesian coordinates from areal coordinates ......................... 193
11.4.4 .................................................. 193
11.4.5 .................................................. 194
11.5 Vector methods in geometry ................................ 195
11.5.1 Menelaus’ theorem, c. 100 A.D. .......................... 195
11.5.2 Ceva’s theorem and converse, 1678 A.D. ....................... 196
11.5.3 Desargues’ perspective theorem, 1648 A.D. ..................... 199
11.5.4 Pappus’ theorem, c. 300 A.D. ............................ 201
11.5.5 Centroid of a triangle .................................. 203
11.5.6 Orthocentre of a triangle ............................... 203
11.5.7 Incentre of a triangle .................................. 205
11.6 Mobile coordinates ....................................... 206
11.6.1 Grassmann’s supplement of a vector ........................ 206
11.6.2 .................................................. 207
11.6.3 Handling a triangle ..................................... 207
11.6.4 Circumcentre of a triangle ................................ 209
11.6.5 Other distinguished points for a triangle ......................... 211
11.6.6 Euler line of a triangle .................................. 215
11.6.7 Similar triangles ...................................... 215
11.6.8 Centroids of similar triangles erected on the sides of a triangle .. 217
11.6.9 Circumcentres of similar triangles on sides of triangle ........... 218
11.6.10 Triangle with vertices the mid-points of sides of given triangle ... 219

About the author

Paddy Barry was born in Co. Westmeath in 1934 and his family moved to Co. Cork five years later. After his secondary school education at Patrician Academy, Mallow he studied at University College, Cork from 1952 to 1957, obtaining a degree of BSc in Mathematics and Mathematical Physics in 1955 and the degree of MSc in 1957. He then did research in complex analysis under the supervision of Professor W. K. Hayman, FRS, at Imperial College of Science and Technology, London (1957–1959) for which he was awarded the degree of PhD in 1960. He took first place in the Entrance Scholarships Examination to University College, Cork in 1952 and was awarded a Travelling Studentship in Mathematical Science at the National University of Ireland in 1957.

He was appointed Instructor in Mathematics at Stanford University, California in 1959–1960. Returning to University College, Cork in 1960 he made his career there, becoming Professor of Mathematics and Head of Department in 1964. He has been Professor Emeritus of Mathematics there from 1999 to date. He participated in the general administration of the College, being a member of the Governing Body on a number occasions, and was the first modern Vice-President of the College from 1975 to 1977. He was also a member of the Senate of the National University of Ireland from 1977 to 1982.

University College, Cork was upgraded to National University of Ireland, Cork in 1997 and both titles are now used.

His mathematical interests expanded in line with his extensive teaching experience. As examiner for matriculation for many years he had to keep in contact with the detail of secondary school mathematics and the present book arose from that context, as it seeks to give a thorough account of the geometry and trigonometry that is done, necessarily incompletely, at school.
Preface

I have for a long time held the view that whereas university courses in algebra, number systems and analysis admirably consolidate the corresponding school material, this is not the case for geometry and trigonometry. These latter topics form an important core component of mathematics, as they underpin analysis in its manifold aspects and applications in classical applied mathematics and sundry types of science and engineering, and motivate other types of geometry, and topology. Yet they are not well treated as university topics, being either neglected or spread over a number of courses, so that typically a student picks up a knowledge of these incidentally and relies mainly on the earlier intuitive treatment at school.

Clearly the treatment of geometry has seriously declined over the last fifty years, in terms of both quantity and quality. Lecturers and authors are faced with the question of what, if anything, should be done to try to restore it to a position of some substance. Bemoaning its fate is not enough, and surely authors especially should ponder what kinds of approach are likely to prove productive.

Pure or synthetic geometry was the first mathematical topic in the field and for a very long time the best established. It was natural for authors to cover as much ground as was feasible, and ultimately there was a large bulk of basic and further geometry. That was understandable in its time but perhaps a different overall strategy is now needed.

Synthetic geometry seems very difficult. In it we do not have the great benefit of symbolic manipulations. It is very taxing to justify diagrams and to make sure of covering all cases. From the very richness of its results, it is difficult to plan a productive approach to a new problem. In the proofs that have come down to us, extra points and segments frequently need to be added to the configuration. It is true that, as in any approach, there are some results which are handled very effectively and elegantly by synthetic methods, but that is certainly not the whole story. On the other hand, what is undeniable is that synthetic geometry really deals with geometry, and it forces attention to, and clarity in, geometrical concepts. It encourages the careful layout of sequential proof. Above all, it has a great advantage in its intuitive visualisation and concreteness.

The plan of this book is to have a basic layer of synthetic geometry, essentially five chapters in all, because of its advantages, and thereafter to diversify as much as possible to other techniques and approaches because of its difficulties. More than that, we assume strong axioms (on distance and angle-measure) so as to have an efficient approach from the start. The other approaches that we have in mind are the use of coordinates, trigonometry, position-vectors and complex numbers. Our emphasis is on clarity of concepts, proof and systematic and complete development of material. The synthetic geometry that we need is what is sufficient to start coordinate geometry and trigonometry, and that takes us as far as the ratio results for triangles and Pythagoras’ theorem. In all, a considerable portion of traditional ground involving straight-lines and circles is covered. The overall approach is innovative as is the detail on trigonometry in Chapter 9 and on what are termed ‘mobile coordinates’ in Chapter 11. Some
new concepts and substantial new notation have been introduced. There is enough for a two-semester course; a one-semester one could be made from Chapters 2-9, with Chapter 7 trimmed back.

My object has been to give an account at once accessible and unobtrusively rigorous. Preparation has been in the nature of unfinished business, stemming from my great difficulties when young in understanding the then textbooks in geometry. I hold that the reasoning in geometry should be as convincing as that in other parts of mathematics. It is too much to hope that there are no errors, mathematical or typographical. I should be grateful to be told of any at the email address p.barry@ucc.ie.

Acknowledgements

I am grateful to students in a succession of classes who responded to this material in its nascent stages, to departmental colleagues, especially Finbarr Holland and Des MacHale, who attended presentations of it, and to American colleagues the late David Rosen of Swarthmore and John Elliott of Fort Kent, Maine, who read an earlier approach of mine to geometry. I am especially grateful to Dr. P.A.J. Cronin, a colleague in our Department of Ancient Classics, for preparing the translations from Greek and Latin in the Glossary on pp. xix-xx.

Paddy Barry

National University of Ireland, Cork,

PREFATORY NOTE TO THE REVISED EDITION

Several changes have taken place since the preparation of this material in the years leading up to 2001. The original publisher HORWOOD was acquired in 2010 by WOODHEAD which in turn was acquired in 2013 by ELSEVIER. However WOODHEAD is retaining its imprint.

The reason for a revised edition was that the stock for the original edition was exhausted. There is not a lot of alteration in this edition, some correction of errors and the strengthening of some proofs apart from Chapter 11 in which there is considerable alteration of detail.

There is a great alteration in the software available and required in mathematical word processing, particularly on those who have relied heavily on pstricks for preparing diagrams, and I owe a huge debt in this regard to my colleagues Paul Keegan, Marc van Dongen, Peter Flynn, Stephen Wills, Ben McKay and Joseph Manning. I also thank Ulrike Fischer, who is a troubleshooter for TeX, and without whose involvement this project would not have been completed.

Paddy Barry

National University of Ireland, Cork,

February, 2015.
Glossary

Greek and Latin roots of mathematical words

acute < L acutus, sharp-pointed (perf. partic. of acure, to sharpen).

addition < L additio, an adding to (addere, to add).

angle < L angulus, corner < Gk agkylos, bent.

area < L area, a vacant space.

arithmetic < Gk arithmetike (sc. tekhne), the art of counting (arithmein, to count; arithmos, number).

axiom < Gk axioma, self-evident principle (axis, to consider worthy; axios, worthy).

calculate < L calculatus, reckoned (perf. partic. of calculare < calculus, pebble).

centre < Gk kentron, sharp point (kentein, to spike).

chord < Gk khorde, string of gut.

circle < L circulus, ring-shaped figure (related to Gk kyklos, ring; kirkos or krikos, ring).

congruent < L congruens (gen. congruentis), agreeing with (pres. partic. of congruere, to agree with).

curve < L curvus (curvare, to bend).

decimal < L (Med) decimalis, of tenths (decima (sc. pars), tenth part; decem, ten).

degree < OF degré < L degredi, descend (de, down; gradii, to step).

diagonal < L diagonalis, diagonal < Gk diagnostos, from angle to angle (dia, through; gonía, angle).

diagram < Gk diagramma, plan, figure indicated by lines (dia, through; gramma, a thing which is drawn; graphein, to draw).

diameter < Gk diametros, diametrical (dia, through; metron, measure).

distance < L distantia, remoteness (distare, to stand apart).

divide < L dividere, to separate.

equal < L equalis, equal (aequare, to make equal; aequis, equal).

element < L elementum, a building stone (elementum, a stone).

example < L exemplum, sample < eximere, to take out.

exponent < L exponens (gen. exponentis), setting forth (pres. partic. of ponere, to set forth; ex, out; ponere to place).

factor < L factor, maker, doer (facere, to make).

focus < L focus, hearth.

fraction < L fractio, a breaking into pieces (frangere, to break).

geometry < Gk geometria, measuring of land (ge, land; metretin, to measure).

graph < Gk graphos, drawing, picture (graphein, to draw).

hypotenuse < Gk hypoteinousa (sc. gramme), the line extending underneath (pres. partic. of hypoteinein, to extend under; gramme, line).

hypothesis < Gk hypothesis, supposition, assumption (hypotithenai, to place beneath).

inclination < L inclinatio, a leaning to one side (inclinare, to cause to lean).

induction < L inductio, a leading into (inducere, to lead in).

isosceles < Gk isoskeles, having equal legs (isos, equal; skelos, leg).

line < L linea, a linen thread (linum, flax < Gk linon).

logic < Gk logike (sc. tekhne), the art of reasoning (logos, reason; logikos, endowed with reason; tekhne, art).

magnitude < L magnitudo, size, greatness (magnus, great).

mathematics < Gk mathematika, things that require mathematical or scientific reasoning (mathema, lesson; mathematikos, mathematical or scientific; manthan ein, to learn).

measure < F mesure < L mensura, measure (metiri, to measure).

minus < L minus, less.

multiply < L multiplicare, multiply (multus, much; plicare, to lay together).

negative < L negativus, denying (negare, to deny).

number < F nombre < L numerus, number.
Glossary

**oblong** < L *oblongus*, longish.

**obtuse** < L *obtusus*, blunted (perf. partic. of *obtundere*, to blunt).

**orthogonal** < Gk *orthogonios*, rectangular (*ortos*, right; *gonia*, angle).

**parallel** < Gk *parallelos*, beside one another (*para*, beside; *allelous*, one another).

**perimeter** < Gk *perimetron*, circumference (*peri* around; *metron*, measure).

**perpendicular** < L *perpendicularum*, plumb-line (*perpendere*, to weigh precisely).

**plane** < L *planum*, level ground (*planus*, level).

**point** < L *punctum*, small hole (*pungere*, to pierce).

**polygon** < Gk *polygonon*, thing with many angles (*polys*, many; *gonia*, angle).

**positive** < L *positivus*, settled (*ponere*, to place).

**postulate** < L *postulare*, to ask for.

**power** < OF *poeir* < L *posse*, to be able.

**product** < L *productus*, brought forth (perf. partic. of *producere*, to bring forth).

**proportion** < L *portio*, comparative relationship (*pro*, according to; *portio*, part).

**quadrangle** < L *quadrangulum*, thing with four angles (*quattuor*, four; *angulus*, angle).

**quotient** < L *quotiens*, how often.

**radius** < L *radius*, rod, spoke of wheel.

**rectangle** < L *rectangulum*, right-angled (*rectus*, right; *angulus*, angle).

**rhombus** < Gk *rhombos*, a device whirled round (*rhembein*, to whirl round).

**science** < L *scientia*, knowledge (*scire*, to know).

**secant** < L *secans* (gen. *secantis*), cutting (*se-care*, to cut).

**square** < OF *esquarre* < L *quattuor*, four.

**subtract** < L *subtractus*, withdrawn (perf. partic. of *subtrahere*, to withdraw).

**sum** < L *summa*, top.

**tangent** < L *tangens* (sc. *linea*) (gen. *tangentis*), touching line (*tangere*, to touch; *linea*, line).

**technical** < Gk *tekhnikos*, artistic, skilful (*tekhne*, art).

**theorem** < Gk *theorema*, thing observed, deduced principle (*theorein*, to observe).

**total** < L *totus*, whole, all.

**trapezium** < Gk *trapezion*, small table (*trapeza*, table).

**triangle** < L *triangulum*, triangle (*tris*, three; *angulus*, angle).

**trigonometry** < Gk *trigonometria*, measurement of triangles (*trigonon*, triangle; *metrein*, to measure).

**vector** < L *vector*, bearer (*vehere*, to bear).

**vertex** < L *vertex*, summit.

1

Preliminaries

1.1 HISTORICAL NOTE

This is one in a long line of textbooks on geometry. While all civilisations seem to have had some mathematical concepts, the most significant very old ones historically were the linked ones of Sumer, Akkad and Babylon, largely in the same region in what is now southern Iraq, and the separate one of Egypt. These are the ones which have left substantial traces of their mathematics, which was largely arithmetic, and geometrical shapes and measurement.

The outstanding contribution to mathematics was in Greece about 600 B.C.–200 B.C. The earlier mathematics conveyed techniques by means of examples, but the Greeks stated general properties of the mathematics they were doing, and organised proof of later properties from ones taken as basic. There was astonishing progress in three centuries and the fruit of that was written up in Euclid’s *The Elements*, c. 300B.C. He worked in Alexandria in Egypt, which country had come into the Greek sphere of influence in the previous century.

Euclid’s *The Elements* is one of the most famous books in the world, certainly the most famous on mathematics. But it was influential widely outside mathematics too, as it was greatly admired for its logical development. It is the oldest writing on geometry of which we have copies by descent, and it lasted as a textbook until after 1890, although it must be admitted that in lots of places and for long periods not very many people were studying mathematics. It should probably be in the Guinness Book of Records as the longest lasting textbook in history.

*The Elements* shaped the treatment of geometry for 2,000 years. Its style would be unfamiliar to us today, as apart from using letters to identify points and hence line-segments, angles and other figures in diagrams, it consisted totally of words. Thus it did not use symbols as we do. It had algebra different from ours in that it said things in words written out in full. Full symbolic algebra as we know it was not perfected until about 1600 A.D. in France, by Vieta and later Descartes. Another very significant feature of *The Elements* was that it did not have numbers ready-made, and used distance or length, angle-measure and area as separate quantities, although links...
between them were worked out.

Among prominent countries, *The Elements* lasted longest in its original style in the U.K., until about 1890. They had started chipping away at it in France in the 16th century, beginning with Petrus Ramus 1515-1572. There is a very readable account of the changes which were made in France in Cajori [3, pages 275 – 289]. These changes mainly involved disimprovements logically; authors brought in concepts which are visually obvious, but they did not provide an account of the properties of these concepts. Authors in France, and subsequently elsewhere, started using our algebra to handle the quantities and this was a major source of advance. One very prominent textbook of this type was *Elements of Geometry* by Legendre, (first edition 1794), which was very influential on the continent of Europe and in the U.S.A. All in all, these developments in France shook things up considerably, and that was probably necessary before a big change could be made.

Although *The Elements* was admired widely and for a long time for its logic, there were in fact logical gaps in it. This was known to the leading mathematicians for quite a while, but it was not until the period 1880-1900 that this geometry was put on what is now accepted as an adequate logical foundation. Another famous book *Foundations of Geometry* by Hilbert (1899) was the most prominent in doing this. The logical completion made the material very long and difficult, and this type of treatment has not filtered down to school-level at all, or even to university undergraduate level except for advanced specialised options.

Another sea-change was started in 1932 by G.D. Birkhoff; instead of building up the real number system via geometrical quantities, he assumed a knowledge of numbers and used that from the start in geometry; this appeared in his ‘ruler postulate’ and ‘protractor postulate’. His approach allowed for a much shorter, easier and more efficient treatment of geometry.

In the 1960’s there was the world-wide shake-up of the ‘New Mathematics’, and since then there are several quite different approaches to geometry available. In this Chapter 1 we do our best to provide a helpful introduction and context, and suggest a re-familiarisation with the geometrical knowledge already acquired.

Logically organised geometry dates from c. 600-300 B.C. in Greece; by c. 350B.C. there was already a history of geometry by Eudemus. From the same period and earlier, date positive integers and the treatment of positive fractions via ratios. The major mathematical topics date from different periods: geometry as just indicated; full algebra from c. 1600 A.D.; full coordinate geometry from c. 1630A.D.; full numbers (negative, rational, decimals) from c. 1600 A.D.; complex numbers from c. 1800 A.D.; calculus from c. 1675 A.D.; trigonometry from c. 200 B.C., although circles of fixed length of radius were used until c. 1700 A.D. when ratios were introduced.

There is an account of the history of geometry of moderate length by H. Eves in [2, pages 165-192]

It should be clear from this history that the Greek contribution to geometry greatly influenced all later mathematics. It was transmitted to us via the Latin language, and we have included a Glossary on pp. xix-xx showing the Greek or Latin roots of
1.2 NOTE ON DEDUCTIVE REASONING

The basic idea of a logical system is that we list up-front the terms and properties that we start with, and thereafter proceed by way of definitions and proofs. There are two main aspects to this.

1.2.1 Definitions

The first aspect concerns specifying what we are dealing with. A definition identifies a new concept in terms of accepted or known concepts. In practice a definition of a word, symbol or phrase $E$ is a statement that $E$ is to be used as a substitute for $F$, the latter being a phrase consisting of words and possibly symbols or a compound symbol. We accept ordinary words of the English language in definitions and what is at issue is the meaning of technical mathematical words or phrases. In attempting a definition, there is no progress if the technical words or symbols in $F$ are not all understood at the time of the definition.

The disconcerting feature of this situation is that in any one presentation of a topic there must be a first definition and of its nature that must be in terms of accepted concepts. Thus we must have terms which are accepted without definition, that is there must be undefined or primitive terms. This might seem to leave us in a hopeless position but it does not, as we are able to assume properties of the primitive terms and work with those.

There is nothing absolute about this process, as a term which is taken as primitive in one presentation of a topic can very well be a defined term in another presentation of that topic, and vice versa. We need some primitive terms to get an approach under way.

1.2.2 Proof

The second aspect concerns the properties of the concepts that we are dealing with. A proof is a finite sequence of statements the first of which is called the hypothesis, and the last of which is called the conclusion. In this sequence, each statement after the hypothesis must follow logically from one or more statements that have been previously accepted. Logically there would be a vicious circle if the conclusion were used to help establish any statement in the proof.

There is also a disconcerting feature of this, as in any presentation of a topic there must be a first proof. That first proof must be based on some statements which are not proved (at least the hypothesis), which are in fact properties that are accepted without proof. Thus any presentation of a topic must contain unproved statements; these are called axioms or postulates and these names are used interchangeably.

Again there is nothing absolute about this, as properties which are taken as axiomatic in one presentation of a topic may be proved in another presentation, and
vice versa. But we must have some axioms to get an approach under way.

1.3 EUCLID’S *The Elements*

1.3.1

*The Elements* involved the earliest surviving deductive system of reasoning, having axioms or postulates and common notions, and proceeding by way of careful statements of results and proofs. Up to c. 1800, geometry was regarded as the part of mathematics which was best-founded logically. But its position was overstated, and its foundations not completed until c. 1880-1900. Meanwhile the foundations of algebra and calculus were properly laid in the 19th century. From c. 1800 on, some editions used algebraic notation in places to help understanding.

1.3.2 Definitions

The Greeks did not appreciate the need for primitive terms, and *The Elements* started with an attempt to define a list of basic terms.

*DEFINITIONS*

1. A **POINT** is that which has no parts, or which has no magnitude.

2. A **LINE** is length without breadth.

3. The **EXTREMITIES** of a line are points.

4. A **STRAIGHT LINE** is that which lies evenly between its extreme points.

5. A **SUPERFICIES** is that which has only length and breadth.

6. The **EXTREMITIES** of a superficies are lines.

7. A **PLANE SUPERFICIES** is that in which any two points being taken, the straight line between them lies wholly in that superficies.

8. A **PLANE ANGLE** is the inclination of two lines to one another in a plane, which meet together, but are not in the same direction.

9. A **PLANE RECTILINEAL ANGLE** is the inclination of two straight lines to one another, which meet together, but are not in the same straight line.

10. When a straight line standing on another straight line, makes the adjacent angles equal to one another, each of the angles is called a **RIGHT ANGLE**; and the straight line which stands on the other is called a **PERPENDICULAR** to it.
11. An **OBTUSE ANGLE** is that which is greater than a right angle.

12. An **ACUTE ANGLE** is that which is less than a right angle.

13. A **TERM** or **BOUNDARY** is the extremity of anything.

14. A **FIGURE** is that which is enclosed by one or more boundaries.

15. A **CIRCLE** is a plane figure contained by one line, which is called the **CIRCUMFERENCE**, and is such that all straight lines drawn from a certain point within the figure to the circumference are equal to one another.

16. And this point is called the **CENTRE** of the circle.

17. A **DIAMETER** of a circle is a straight line drawn through the centre, and terminated both ways by the circumference.

18. A **SEMICIRCLE** is the figure contained by a diameter and the part of the circumference cut off by the diameter.

19. A **SEGMENT** of a circle is the figure contained by a straight line and the circumference which cuts it off.

20. **RECTILINEAL FIGURES** are those which are contained by straight lines.

21. **TRILATERAL FIGURES**, or **TRIANGLES**, by three straight lines.

22. **QUADRILATERAL FIGURES** by four straight lines.

23. **MULTILATERAL FIGURES**, or **POLYGONS**, by more than four straight lines.

24. Of three-sided figures, an **EQUILATERAL TRIANGLE** is that which has three equal sides.

25. An **ISOSCELES TRIANGLE** is that which has two sides equal.

26. A **SCALENE TRIANGLE** is that which has three unequal sides.

27. A **RIGHT-ANGLED TRIANGLE** is that which has a right angle.

28. An **OBTUSE-ANGLED TRIANGLE** is that which has an obtuse angle.

29. An **ACUTE-ANGLED TRIANGLE** is that which has three acute angles.

30. Of four-sided figures, a **SQUARE** is that which has all its sides equal, and all its angles right angles.

31. An **OBLONG** is that which has all its angles right angles, but not all its sides equal.
32. A **RHOMBUS** is that which has all its sides equal, but its angles are not right angles.

33. A **RHOMBOID** is that which has its opposite sides equal to one another, but all its sides are not equal, nor its angles right angles.

34. All other four-sided figures besides these are called **TRAPEZIUMS**.

35. **PARALLEL STRAIGHT LINES** are such as are in the same plane, and which being produced ever so far both ways do not meet.

Although in *The Elements* these definitions were initially given, some of these were treated just like motivations (for instance, for a point where no use was made of the fact that ‘it has no parts’) whereas some were genuine definitions (like that of a circle, where the defining property was used). Our definitions will differ in some respects from these.

1.3.3 Postulates and common notions

The Greeks understood the need for axioms, and these were laid out carefully in *The Elements*. *The Elements* has two lists, a first one of **POSTULATES** and a second one of **COMMON NOTIONS**. It is supposed by some writers that Euclid intended his list of **POSTULATES** to deal with concepts which are mathematical or geometrical, and the second list to deal with concepts which applied to science generally.

**POSTULATES**

Let it be granted,

1. That a straight line may be drawn from any one point to any other point.
2. That a terminated straight line may be produced to any length in a straight line.
3. And that a circle may be described from any centre, at any distance from that centre.
4. All right angles are equal to one another.
5. If a straight line meet two straight lines, so as to make the two interior angles on the same side of it taken together less than two right angles, these straight lines, being continually produced, shall at length meet on that side on which are the angles which are less than two right angles.

**COMMON NOTIONS**

1. Things which are equal to the same thing are equal to one another.
2. If equals be added to equals the wholes are equals.

3. If equals be taken from equals the remainders are equal.

4. Magnitudes which coincide with one another, [that is, which exactly fill the same space] are equal to one another.

5. The whole is greater than its part.

1.3.4

*The Elements* attempted to be a logically complete deductive system. There were earlier Elements but these have not survived, presumably because they were outclassed by Euclid’s.

*The Elements* are charming to read, proceed very carefully by moderate steps and within their own terms impart a great sense of conviction. The first proposition is to describe an equilateral triangle on \([A, B]\). With centre \(A\) a circle is described passing through \(B\), and with centre \(B\) a second circle is described passing through \(A\). If \(C\) is a point at which these two circles cut one another, then we take the triangle with vertices \(A, B, C\).

It is ironical that, with *The Elements* being so admired for their logical proceeding, there should be a gap in the very first proposition. The postulates and common notions did not make any provisions which would ensure that the two circles in the proof would have a point in common. This may seem a curious choice as a first proposition, dealing with a very special figure. But in fact it is used immediately in Proposition 2, from a given point to lay off a given distance.

The main logical lack in *The Elements* was that not enough assumed properties were listed, and this fact was concealed through the use of diagrams.

1.3.5 Congruence

Two types of procedure in *The Elements* call for special comment. The first is the method of *superposition* by which one figure was envisaged as being moved and placed exactly on a second figure. The second is the process of *construction* by which figures were not dealt with until it was shown by construction that there actually was such a type of figure. In the physical constructions, what were allowed to be used were straight edges and compasses.

The notion of *superposition* is basic to Euclid’s treatment of figures. It is visualised that one figure is moved physically and placed on another, fitting perfectly. We use the term *congruent* figures when this happens. Common Notion 4 is to be used in this connection. This physical idea is clearly extraneous to the logical set-up of primitive and defined terms, assumed and proved properties, and is not a formal part of modern treatments of geometry. However it can be used in motivation, and properties motivated by it can be assumed in axioms.
1.3.6 Quantities or magnitudes

*The Elements* spoke of one segment (then called a line) being equal to or greater than another, one region being equal to or greater than another, and one angle being equal to or greater than another, and this indicates that they associated a magnitude with each segment (which we call its length), a magnitude with each region (which we call its area), and a magnitude with each angle (which we call its measure). They did not define these magnitudes or give a way of calculating them, but they gave sufficient properties for them to be handled as the theory was developed. In the case of each of them the five common notions were supposed to apply.

Thus in *The Elements*, the *quantities* for which the Common Notions are intended are *distance* or equivalently *length* of a segment, *measure* of an angle and *area* of a region. These are not taken to be known, either by assumption or definition, but congruent segments are taken to have equal lengths, congruent angles are taken to have equal measures, and congruent triangles are taken to have equal areas. Thus equality of lengths of segments, equality of measures of angles, and equality of areas of triangles are what is started with. Treatment of area is more complicated than the other two, and triangles equal in area are not confined to congruent triangles. Addition and subtraction of lengths are to be handled using Common Notions 1, 2, 3 and 4; so are addition and subtraction of angle measures; so are addition and subtraction of area.

Taking a unit length, there is a long build-up to the length of any segment. They reached the stage where if some segment were to be chosen to have length 1 the length of any segment which they encountered could be found, but this was not actually done in *The Elements*.

Taking a right-angle as a basic unit, there was a long build-up to handling any angle. They reached the stage where if a right-angle was taken to have measure $90^\circ$, the measure of any angle which they encountered could be found, but this was not actually done.

There is a long build up to the area of figures generally. The regions which they considered were those which could be built up from triangles, and they reached the stage where if some included region were chosen to have area 1 the area of any included region could be found. This is not actually completed in *The Elements* but the materials are there to do it with.

All this shows that *The Elements* although very painstaking, thorough and exact were also rather abstract. It should be remembered that the Greeks did not have algebra as we have, and used geometry to do a lot of what we do by algebra. In particular, considering the area of a rectangle was their way of handling multiplication of quantities. Traditionally in arithmetic the area of a rectangle was dealt with as the product of the length and the breadth, that is by multiplication of two numbers. However, reconciling the geometrical treatment of area with the arithmetical does not seem to have been handled very explicitly in books, not even when from 1600 A.D. onwards real numbers were being detached from the ‘quantities’ of Euclid.
1.4 OUR APPROACH

1.4.1 Type of course

Very scholarly courses in geometry assume as little as possible, and as a result are long and difficult. Shorter and easier courses have more or stronger assumptions, and correspondingly less to prove. What is difficult in a thorough course of geometry is not the detail of proof usually included, but rather, first of all, locational viz. to prove that points are where diagrams suggest they are, that is to verify the diagrams, and secondly to be sure of covering all cases.

In particular, the type of approach which assumes that distance, angle-measure and area are different ‘quantities’ leads to a very long and difficult treatment of geometry. To make things much easier and shorter, we shall suppose that we know what real numbers are, and deal with distance/length and angle-measure as basic concepts given in terms of real numbers, and develop their properties. Moreover, we shall define area in terms of lengths.

What we provide, in fact, is a combination of Euclid’s original course and a modification of an alternative treatment due to the American mathematician G.D. Birkhoff in 1932.

1.4.2 Need for preparation

What this course aims to do is to revise and extend the geometry and trigonometry that has been done at school. It gives a careful, thorough and logical account of familiar geometry and trigonometry. At school, a complete, logically adequate treatment of geometry is out of the question. It would be too difficult and too long, unattractive and not conducive to learning geometry; it would tend rather to put pupils off.

Thus this is not a first course in geometry. It is aimed at third level students, who should have encountered the basic concepts at secondary, or even primary, school. It starts geometry and trigonometry from scratch, and thus is self-contained to that extent.

But it is demanding because of a sustained commitment to deductive reasoning. In preparation the reader is strongly urged to start by revising the geometry and trigonometry which was done at school, at least browsing through the material. It would also be a good idea to read in some other books some descriptive material on geometry, such as the small amount in Ledermann and Vajda [10, pages 1 – 26], or the large amount in Wheeler and Wheeler [13, Chapters 11 – 15]. Similarly trigonometry and vectors can be revised from McGregor, Nimmo and Stothers [11, pages 99 – 123, 279 – 331].

It would moreover be helpful to practise geometry by computer, e.g. by using software systems such as The Geometer’s Sketchpad or Cabri-Géomètre. Material which can be found in elementary books should be gone over, and also a look forwards could be had to the results in this book.
1.5 REVISION OF GEOMETRICAL CONCEPTS

1.5.1

As part of the preliminary programme, we now include a review of the basic concepts of geometry. Geometry should be thought of as arising from an initial experimental and observational stage, where the figures are looked at and there is a great emphasis on a visual approach.

1.5.2 The basic shapes

1. The plane $\Pi$ is a set, the elements of which are called points. Certain subsets of $\Pi$ are called lines.

   By observation, given any distinct points $A, B \in \Pi$, there is a unique line to which $A$ and $B$ both belong. It is denoted by $AB$.

   2. Given distinct points $A$ and $B$, the set of points consisting of $A$ and $B$ themselves and all the points of the line $AB$ which are between $A$ and $B$ is called a segment, and denoted by $[A, B]$.

\begin{figure}[h]
\centering
\includegraphics[width=0.4\textwidth]{line}
\caption{A line $AB$. The arrows indicate that the line is to be continued unendingly.}
\end{figure}

\begin{figure}[h]
\centering
\includegraphics[width=0.4\textwidth]{segment}
\caption{A segment $[A, B]$.}
\end{figure}

NOTE. Note that the modern mathematical terminology differs significantly from that in The Elements. What was called a ‘line’ is now called a segment, and we have added the new concept of ‘line’. This is confusing, but the practice is well established. In ordinary English and in subjects cognate to mathematics, ‘line’ has its old meaning.

3. The set consisting of the point $A$ itself and all the points of the line $AB$ which are on the same side of $A$ as $B$ is, is called a half-line, and denoted by $[A, B]$. If $A$ is between $B$ and $C$, then the half-lines $[A, B]$ and $[A, C]$ are said to be opposite.
Sec. 1.5  
Revision of geometrical concepts

4. If the points $B, C$ are distinct from $A$, then the pair of half-lines 
$\{[A, B], [A, C]\}$ is called an angle-support and denoted by $|BAC|$; if $[A, B]$ and $[A, C]$ are opposite half-lines, then $|BAC|$ is called a straight angle-support. In each case $A$ is called its vertex, $[A, B]$ and $[A, C]$ its arms.

5. The set of all the points on, or to one side of, a line $AB$ is called a closed half-plane, with edge $AB$.

6. If the points $A, B, C$ are not collinear, then the set of points which are in both the closed half-plane with edge $AB$, containing $C$, and the closed half-plane with edge $AC$, containing $B$, is called the interior region of $|BAC|$ and denoted by $\mathcal{I}(|BAC|)$; also $(\Pi \setminus \mathcal{I}(|BAC|)) \cup |BAC|$ is called the exterior region of $|BAC|$ and denoted by $\mathcal{E}(|BAC|)$. When $C \in [A, B]$ the interior and exterior regions of $|BAC|$ are taken to be $[A, B]$ and $\Pi$, respectively.
7. If $|BAC|$ is a non-straight angle-support, then the couples 
$(|BAC|, \mathcal{I}(|BAC|)), (|BAC|, \mathcal{R}(|BAC|))$, are called the wedge-angle and reflex-angle, respectively, with support $|BAC|$; this wedge-angle is denoted by $\angle BAC$. Thus a wedge-angle is a pair of arms in association with an interior region, while a reflex-angle is a pair of arms combined with an exterior region.

If $|BAC|$ is a straight angle-support, and $\mathcal{H}_1, \mathcal{H}_2$ are the closed half-planes with edge the line $AB$, then the couples $(|BAC|, \mathcal{H}_1), (|BAC|, \mathcal{H}_2)$, are called the straight-angles with support $|BAC|$. If $C \in [A, B]$ then the wedge-angle $\angle BAC = \angle BAB$ is called a null-angle, and the reflex-angle with support $|BAB|$ is called a full-angle.

NOTE. The reason we call $|BAC|$ an angle-support and not an angle is that it supports two angles. If we were confining ourselves to pure geometry, and not concerned to go forward to coordinate geometry and trigonometry, we could confine ourselves to wedge and straight angles. Even more if we were to confine ourselves to the angles...
Revision of geometrical concepts

in triangles, we could take $|BAC| = [A, B \cup A, C]$. However when $A$ is between $B$ and $C$, this would result in a straight-angle being a line, and it would not have a unique vertex. In the early part of our course, we can confine our attention to wedge and straight angles.

![Figure 1.8. Supports bearing two angles each.]

8. If $A$ is between $B$ and $C$ and $D \notin BC$, the wedge-angles $\angle BAD$, $\angle CAD$ are called supplementary. If $A, B, C$ are not collinear, and $A$ is between $B$ and $B_1$, and $A$ is between $C$ and $C_1$, then the wedge-angles $\angle BAC, \angle B_1AC_1$ are called opposite angles at a vertex.

![Figure 1.9. Supplementary angles.]

9. If $A, B, C$ are non-collinear points and $[A, D]$ is in the interior region of $|BAC|$, then $[A, D]$ is said to be between $[A, B]$ and $[A, C]$.

![Figure 1.10. $[A, D]$ between $[A, B]$ and $[A, C]$.]

10. If $A, B, C$ are non-collinear points, let $\mathcal{H}_1$ be the closed half-plane with edge $BC$, containing $A$, $\mathcal{H}_3$ be the closed half-plane with edge $CA$, containing $B$, $\mathcal{H}_5$ be the closed half-plane with edge $AB$, containing $C$. Then the intersection $\mathcal{H}_1 \cap \mathcal{H}_3 \cap$.
$\mathcal{H}_2$ is called a triangle. The points $A, B, C$ are called its vertices and the segments $[B,C], [C,A], [A,B]$ its sides. If a vertex is not the end-point of a side (e.g. the vertex $A$ and the side $[B,C]$), then the vertex and side are said to be opposite each other. We denote the triangle with vertices $A, B, C$ by $[A,B,C]$.

If at least two sides of a triangle have equal lengths, then the triangle is called isosceles.

![Figure 1.11. A triangle $[A,B,C]$.](image1)

![An isosceles triangle.](image2)

11. Let $A, B, C, D$ be points no three of which are collinear, and such that $[A,C] \cap [B,D] \neq \emptyset$. For this let $\mathcal{H}_1$ be the closed half-plane with edge $AB$, containing $C$, $\mathcal{H}_3$ be the closed half-plane with edge $BC$, containing $D$, $\mathcal{H}_5$ be the closed half-plane with edge $CD$, containing $A$, $\mathcal{H}_7$ be the closed half-plane with edge $DA$, containing $B$. Then the intersection $\mathcal{H}_1 \cap \mathcal{H}_3 \cap \mathcal{H}_5 \cap \mathcal{H}_7$ is called a convex quadrilateral.

The points $A, B, C, D$ are called its vertices, the segments $[A,B], [B,C], [C,D], [D,A]$ its sides, and the segments $[A,C], [B,D]$ its diagonals. Two vertices which have a side in common are said to be adjacent, and two vertices which have a diagonal in common are said to be opposite. Thus $A$ and $B$ are adjacent as they both belong to $[A,B]$ which is a side; $A$ and $C$ are opposite as they both belong to $[A,C]$ which is a diagonal.

Two sides which have a vertex in common are said to be adjacent, and two sides which do not have a vertex in common are said to be opposite. Thus the sides $[A,B], [D,A]$ are adjacent as the vertex $A$ belongs to both, while the sides $[A,B], [C,D]$ are opposite as none of the vertices belongs to both of them. The wedge angles $\angle DAB, \angle ABC, \angle BCD, \angle CDA$ are called the angles of the convex quadrilateral; two of these angles are said to be adjacent or opposite according as their two vertices are adjacent or opposite vertices of the convex quadrilateral.

We denote the convex quadrilateral with vertices $A, B, C, D$, with $A$ and $C$ opposite, by $[A,B,C,D]$. 
1.5.3 Distance; degree-measure of an angle

1. With each pair $(A, B)$ of points we associate a non-negative real number $|A, B|$, called the distance from $A$ to $B$ or the length of the segment $[A, B]$. In all cases $|B, A| = |A, B|$. By observation, given any non-negative real number $k$, and any half-line $[A, B]$ there is a unique point $P \in [A, B]$ such that $|A, P| = k$.

By observation, if $Q \in [P, R]$ then $|P, Q| + |Q, R| = |P, R|$. In all cases $|A, A| = 0$, while $|A, B| > 0$ if $A \neq B$.

2. Given distinct points $A$ and $B$, choose the point $C \in [A, B]$ so that $|A, C| = \frac{1}{2}|A, B|$. Then $C$ is between $A$ and $B$ and

$$|C, B| = |A, B| - |A, C| = |A, B| - \frac{1}{2}|A, B| = \frac{1}{2}|A, B| = |A, C|.$$  

The point $C$ which is on the line $AB$ and equidistant from $A$ and $B$, is called the mid-point of $A$ and $B$. It is also called the mid-point of the segment $[A, B]$.

---

**Figure 1.12.** A convex quadrilateral.

**Figure 1.13.** Laying off a distance $k$.  
**Figure 1.14.** Mid-point of $A$ and $B$.
3. With each wedge-angle $\angle BAC$ we associate a non-negative number, called its degree-measure, denoted by $|\angle BAC|^\circ$, and for each straight-angle $\alpha$ we take $|\alpha|^\circ = 180$.

![Figure 1.15. Addition of angle-measures.](image)

By observation, we note that if $A, B, C$ are non-collinear and $[A, D]$ is between $[A, B]$ and $[A, C]$, then $|\angle BAD|^\circ + |\angle CAD|^\circ = |\angle BAC|^\circ$, while if $[A, B]$ and $[A, C]$ are opposite and $D \notin AB$, then $|\angle BAD|^\circ + |\angle CAD|^\circ = 180$.

By observation, given any number $k$ with $0 \leq k < 180$ and any half-line $[A, B]$, on each side of the line $AB$ there is a unique wedge-angle $\angle BAC$ with $|\angle BAC|^\circ = k$. In all cases $|\angle BAB|^\circ = 0$, so that the degree-measure of each null angle is 0, while if $\angle BAC$ is not null then $|\angle BAC|^\circ > 0$.

It follows from the foregoing, that if $\angle BAD$ is any wedge-angle then $|\angle BAD|^\circ < 180$, and that if $\angle BAD$, $\angle CAD$ are supplementary angles, then $|\angle CAD|^\circ = 180 - |\angle BAD|^\circ$.

4. Given points $B$ and $C$ distinct from $A$ such that $C \notin [A, B]$, we can choose a point $D$ such that $|\angle BAD|^\circ$ is equal to half the degree-measure of the wedge or straight angle with support $[BAC]$. Then for all points $P \neq A$ on the line $AD$ we have $|\angle BAP|^\circ = |\angle PAC|^\circ$. We call $AP$ the mid-line or bisector of the support $[BAC]$.
5. Any angle $\angle BAC$ such that $0 < |\angle BAC|^{\circ} < 90$ is called acute, such that $|\angle BAC|^{\circ} = 90$ is called right, and such that $90 < |\angle BAC|^{\circ} < 180$ is called obtuse.

If $\angle BAC$ is a right-angle, then the lines $AB$ and $AC$ are said to be perpendicular to each other, written $AB \perp AC$.

1.5.4 Our treatment of congruence

If $[A, B, C]$, $[A', B', C']$ are triangles such that

$$|B, C| = |B', C'|, |C, A| = |C', A'|, |A, B| = |A', B'|,$$

$$|\angle BAC|^{\circ} = |\angle B'A'C'|^{\circ}, |\angle CBA|^{\circ} = |\angle C'B'A'|^{\circ}, |\angle ACB|^{\circ} = |\angle A'C'B'|^{\circ},$$

then we say by way of definition that the triangle $[A, B, C]$ is congruent to the triangle $[A', B', C']$. Behind this concept is the physical idea that $[A, B, C]$ can be placed on $[A', B', C']$, fitting it exactly.

By observation if $[A, B, C]$, $[A', B', C']$ are such that

$$|C, A| = |C', A'|, |A, B| = |A', B'|, |\angle BAC|^{\circ} = |\angle B'A'C'|^{\circ},$$

then $[A, B, C]$ is congruent to $[A', B', C']$. This is known as the SAS (side, angle, side) condition for congruence of triangles.

Similarly by observation if $[A, B, C]$, $[A', B', C']$ are such that

$$|B, C| = |B', C'|, |\angle CBA|^{\circ} = |\angle C'B'A'|^{\circ}, |\angle BCA|^{\circ} = |\angle B'C'A'|^{\circ},$$
then \([A, B, C]\) is congruent to \([A', B', C']\). This is known as the ASA (angle, side, angle) condition for congruence of triangles.

It can be proved that if \(T\) and \(T'\) are triangles with vertices \(\{A, B, C\}\), \(\{A', B', C'\}\), respectively, for which

\[
|B, C| = |B', C'|, |C, A| = |C', A'|, |A, B| = |A', B'|, 
\]

then \(T\) is congruent to \(T'\). This is known as the SSS(side-side-side) principle of congruence.

### 1.5.5 Parallel lines

1. Distinct lines \(l, m\) are said to be parallel if \(l \cap m = \emptyset\); this is written as \(l \parallel m\). We also take \(l \parallel l\).

By observation, given any line \(l\) and any point \(P\) there cannot be more than one line \(m\) through \(P\) which is parallel to \(l\).

It can be shown that two lines are parallel if and only if alternate angles made by a transversal, as indicated, are equal in magnitude, or equivalently, if and only if corresponding angles made by a transversal are equal in magnitude.

2. A convex quadrilateral in which opposite side-lines are parallel to each other is called a parallelogram. A parallelogram in which adjacent side-lines are perpendicular to each other is called a rectangle.
1.6 PRE-REQUISITES

Although this book re-starts geometry and trigonometry from the beginning, it does not take mathematics from a start. Consequently there is material from other parts of mathematics which is assumed known. This also should be revised at the start, or at the appropriate time when it is needed.

At the beginning, we presuppose a moderate knowledge of set theory, sufficient to deal with sets, relations and functions, in particular order and equivalence relations. From Chapter 3 on we assume a knowledge of the real number system, and the elementary algebra involved. Later requirements come in gradually.

1.6.1 Set notation

For set notation we refer to Smith [12, pages 1 – 38]. We mention that we use the word function where it uses map. We should also like to emphasise the difference between a set \( \{a,b\} \) and a couple or ordered pair \((a,b)\). In a set, the order of the elements does not matter, so that \( \{a,b\} = \{b,a\} \) in all cases, and

\[
\{a,b\} = \{c,d\}
\]

if and only if either

\[
a = c \quad \text{and} \quad b = d
\]

or

\[
a = d \quad \text{and} \quad b = c.
\]

In a couple \((a,b)\) it matters which is first and which is second. Thus \((a,b) \neq (b,a)\) unless \(a = b\), and

\[
(a,b) = (c,d)
\]

if and only if

\[
a = c \quad \text{and} \quad b = d.
\]
1.6.2 Classical algebra

We need a knowledge of the real number system and the complex number system, and the classical algebra involving these, up to dealing with quadratic equations and two simultaneous linear equations in two unknowns. For this very elementary material there is an ample provision of textbooks entitled College Algebra by international publishers.

1.6.3 Other algebra

For matrices and determinants we refer to Smith [12, pages 95 – 124] and McGregor, Nimmo and Stothers [11, pages 243 – 278], and for the little that we use on group theory to Smith [12, pages 125 – 152].

1.6.4 Distinctive property of real numbers among fields

For the properties that distinguish the field of real numbers from other ordered fields, we refer to Smith [12, pages 153 – 196].
Basic shapes of geometry

COMMENT. Geometry deals with our intuitions as to the physical space in which we exist, with the properties of the shapes and sizes of bodies as mathematically abstracted. It differs from set theory in that in geometry there are distinguished or special subsets, and relations involving them. To start with we presuppose a moderate knowledge of set theory, sufficient to deal with sets, relations and functions. From Chapter 3 on we assume a knowledge of the real number system, and the elementary algebra involved.

In this first chapter we introduce the plane, points, lines, natural orders on lines, and open half-planes as primitive concepts, and in terms of these develop other special types of geometrical sets.

2.1 LINES, SEGMENTS AND HALF-LINES

2.1.1 Plane, points, lines

Primitive Terms. Assuming the terminology of sets, the plane, denoted by Π, is a universal set the elements of which are called points. Certain subsets of Π are called (straight) lines. We denote by Λ the set of all these lines.

Axiom A₁. Each line is a proper non-empty subset of Π. For each set \{A, B\} of two distinct points in Π, there is a unique line in Λ to which A and B both belong.

We denote by AB the unique line to which distinct points A and B belong, so that A ∈ AB and B ∈ AB. It is an immediate consequence of Axiom A₁ that AB = BA; that if C and D are distinct points and both belong to the line AB, then AB = CD; and that if A, B are distinct points, both on the line l and both on the line m, then l = m.

Furthermore if l, m are any two lines in Λ, then either

\[ l \cap m = \emptyset, \]
or

\[ l \cap m \] is a singleton,

or

\[ l = m \] and in this last case \( l \cap m = l = m \).

Moreover the plane \( \Pi \) is not a line, as each line is a proper subset of \( \Pi \).

If three or more points lie on one line we say that these points are **collinear**. If one point lies on three or more lines we say that these lines are **concurrent**.

### 2.1.2 Natural order on a line

**COMMENT.** The two intuitive senses of motion along a line give us the original examples of linear (total) orders, and we refer to these as the two natural orders on that line. On a diagram the sense of a double arrow gives one natural order on \( l \), while the opposite sense would yield the other natural order on \( l \). We now take natural order as a primitive term, and go on to define segments and half-lines in terms of this and our existing terms.

---

**Primitive Term.** On each line \( l \in \Lambda \) there is a binary relation \( \leq_l \), which we refer to as a **natural order** on \( l \). We read \( A \leq_l B \) as ‘\( A \) precedes or coincides with \( B \) on \( l \)’.

**AXIOM A\(_2\).** Each natural order \( \leq_l \) has the properties:-

(i) \( A \leq_l A \) for all points \( A \in l \);

(ii) if \( A \leq_l B \) and \( B \leq_l C \) then \( A \leq_l C \);

(iii) if \( A \leq_l B \) and \( B \leq_l A \), then \( A = B \);

(iv) for any points \( A, B \in l \), either \( A \leq_l B \) or \( B \leq_l A \).

**COMMENT.** We refer to (i), (ii), (iii) in A\(_2\) as the reflexive, transitive and antisymmetric properties, respectively, of a binary relation; property (iii) can be reworded as, if \( A \leq_l B \) and \( A \neq B \) then \( B \not\leq_l A \). A binary relation with these three properties is commonly called a partial order. A binary relation with all four properties (i), (ii), (iii) and (iv) in A\(_2\) is commonly called a linear order or a total order.
2.1.3 Reciprocal orders

If \( A \preceq_I B \) we also write \( B \succeq_I A \) and read this as ‘\( B \) succeeds or coincides with \( A \) on \( l \)’. Then \( \succeq_I \) is also a total order on \( l \), i.e. \( \succeq_I \) satisfies \( A_2(i), (ii), (iii) \) and (iv), as can readily be checked as follows.

First, on interchanging \( A \) and \( B \) in \( A_2(i) \), we have \( A \succeq_I A \) for all \( A \in l \). Secondly, suppose that \( A \succeq_I B \) and \( B \succeq_I C \); then \( C \preceq_I B \) and \( B \preceq_I A \), so by \( A_2(ii) \) \( C \preceq_I A \); hence \( A \succeq_I C \). Thirdly, suppose that \( A \succeq_I B \) and \( B \succeq_I A \); then \( B \preceq_I A \) and \( A \preceq_I B \) so by \( A_2(iii) \) \( A = B \). Finally, let \( A, B \) be any points on \( l \); by \( A_2(iv) \), either \( A \preceq_I B \) or \( B \preceq_I A \) and so either \( B \succeq_I A \) or \( A \succeq_I B \).

We say that \( \succeq_I \) is reciprocal to \( \preceq_I \). If now we start with \( \succeq_I \) and let \( \preceq_I \) be its reciprocal we have \( A \succeq_I B \) if \( B \succeq_I A \); then we have \( A \succeq_I B \) if and only if \( A \preceq_I B \). Thus \( \succeq_I \) coincides with \( \preceq_I \), and so the reciprocal of \( \succeq_I \) is \( \preceq_I \).

The upshot of this is that \( \preceq_I \) and \( \succeq_I \) are a pair of total orders on \( l \), each the reciprocal of the other. There is no natural way of singling out one of \( \preceq_I \), \( \succeq_I \) over the other, and the notation is equally interchangeable as we could have started with \( \preceq_I \). Having this pair is a nuisance but it is unavoidable, and we try to minimise the nuisance as follows. Given distinct points \( A \) and \( B \), let \( l = AB \). Then exactly one of \( A \preceq_I B \), \( A \succeq_I B \) holds; for by \( A_2(iv) \) either \( A \preceq_I B \) or \( A \succeq_I B \), and by \( A_2(iii) \) both cannot hold as that would imply that \( A = B \). Thus we can choose the natural order on \( l \) in which \( A \) precedes \( B \), by taking \( \preceq_I \) when \( A \preceq_I B \), and by taking \( \succeq_I \) when \( A \succeq_I B \); we will use the notation \( \preceq_I \) for this natural order.

Let \( A \) and \( B \) be distinct points in \( \Pi \), let \( l = AB \) and \( A \preceq_I B \). Let \( C \) be a point of \( l \), distinct from \( A \) and \( B \). Then exactly one of

\[(a) \ C \preceq_I A \preceq_I B, \quad (b) \ A \preceq_I C \preceq_I B, \quad (c) \ A \preceq_I B \preceq_I C, \]

holds.

**Proof.** If \( C \preceq_I A \) then clearly (a) holds. If \( C \preceq_I A \) is false, then by \( A_2(iv) \) \( A \preceq_I C \); by \( A_2(iv) \) we have moreover either \( C \preceq_I B \) or \( B \preceq_I C \), and these yield, respectively, (b) and (c). Thus at least one of (a), (b), (c) holds.

On the other hand, if (a) and (b) hold, we have \( A = C \) by \( A_2(iii) \) and this contradicts our assumptions. Similarly if (b) and (c) hold we would have \( B = C \). Finally if (a) and (c) hold, from (a) we have \( C \preceq_I B \) by \( A_2(ii) \) and then \( B = C \).

2.1.4 Segments

**Definition.** For any points \( A, B \in \Pi \), we define the segments \([A, B]\) and \([B, A]\) as follows. Let \( l \) be a line such that \( A, B \in l \) and \( \preceq_I, \succeq_I \) a pair of reciprocal natural orders on \( l \). Then if

\[ A \preceq_I B \quad \text{so that} \quad B \succeq_I A, \]

we define

\[ [A, B] = \{ P \in l : A \preceq_I P \preceq_I B \} = \{ P \in l : A \preceq_I P \text{ and } P \preceq_I B \}, \]

\[ [B, A] = \{ P \in l : B \succeq_I P \succeq_I A \}, \]
while if \[ B \leq_l A \] so that \[ A \geq_l B, \] (2.1.2) we define

\[
[B,A] = \{ P \in l : B \leq_l P \leq_l A \},
\]

\[
[A,B] = \{ P \in l : A \geq_l P \geq_l B \}.
\]

We should use a more complete notation such as \([A,B]_{\leq_l \geq_l,} [B,A]_{\leq_l \geq_l,} \) but make do with the less precise one. Note that (2.1.2) comes from (2.1.1) on interchanging \(A\) and \(B\), or on interchanging \(\leq_l\) and \(\geq_l\).

When \(A \neq B\), by \(A_1 l = AB\); by \(A_2(iv)\) at least one of (2.1.1) and (2.1.2) holds, and by \(A_2(iii)\) only one of (2.1.1) and (2.1.2) holds.

When \(A = B\), \(l\) can be any line through \(A\), and we find that \(\{ P \in l : A \leq_l P \leq_l A \} = \{ A \}, \{ P \in l : A \geq_l P \geq_l A \} = \{ A \},\) for the singleton \(\{ A \}\). To see this we note that \(A \leq_l A \leq_l A\) by \(A_2(i)\), while if \(A \leq_l P \leq_l A\) then \(P = A\) by \(A_2(iii)\). The same argument holds for \(\geq_l\). Thus \([A,A] = \{ A \}\).

**Figure 2.3.** A segment \([A,B]\).

Segments have the following properties:-

(i) If \(A \neq B\), then \([A,B] \subset AB\).

(ii) \(A,B \in [A,B]\) for all \(A,B \in \Pi\).

(iii) \([A,B] = [B,A]\) for all \(A,B \in \Pi\).

(iv) If \(C,D \in [A,B]\) then \([C,D] \subset [A,B]\).

(v) If \(A,B,C\) are distinct points on a line \(l\), then precisely one of

\[
A \in [B,C], \ B \in [C,A], \ C \in [A,B],
\]

holds.

**Proof.** In each case we suppose that \(A \leq_l B\) so that we have (2.1.1) above; otherwise replace \(\leq_l\) by \(\geq_l\) throughout to cover (2.1.2).

(i) By \(A_1, l = AB\) so \([A,B]\) is a set of points on \(AB\).

(ii) By \(A_2(i)\) \(A \leq_l A \leq_l B\) and \(A \leq_l B \leq_l B\).

(iii) As \(A \leq_l B\), then \(B \geq_l A\) so \([B,A] = \{ P \in l : B \geq_l P \geq_l A \}\). Now if \(P \in [A,B]\), then \(A \leq_l P\) and \(P \leq_l B\). It follows that \(B \geq_l P\) and \(P \geq_l A\). Thus \(P \in [B,A]\) and so \([A,B] \subset [B,A]\). By a similar argument \([B,A] \subset [A,B]\) and so \([A,B] = [B,A]\).
(iv) Let \( C, D \in [A, B] \) so that \( A \leq_l C \leq_l B \) and \( A \leq_l D \leq_l B \). By \( A_2 \)(iv) either \( C \leq_l D \) or \( D \leq_l C \).

If \( C \leq_l D \) and \( P \in [C, D] \), then \( C \leq_l P \leq_l D \). Thus \( A \leq_l C, C \leq_l P \) so by \( A_2 \)(ii), \( A \leq_l P \). Also \( P \leq_l D \), \( D \leq_l B \) so by \( A_2 \)(ii) \( P \leq_l B \). Thus \( P \in [A, B] \).

If \( D \leq_l C \), we interchange \( C \) and \( D \) in the last paragraph.

(v) This follows immediately from 2.1.3.

2.1.5 Half-lines

**Definition.** Given a line \( l \in \Lambda \), a point \( A \in l \) and a natural order \( \leq_l \) on \( l \), then the set

\[
\rho(l, A, \leq_l) = \{ P \in l : A \leq_l P \},
\]

is called a **half-line** or **ray** of \( l \), with **initial point** \( A \).

Given distinct points \( A, B \) let \( \leq_l \) be the natural order on \( l = AB \) for which \( A \leq_l B \); then we also use the notation \( [A, B] \) for \( \rho(l, A, \leq_l) \).

![Figure 2.4. A half-line [A, B].](image)

![Opposite half-lines.](image)

As \( \geq_l \) is also a natural order on \( l \),

\[
\rho(l, A, \geq_l) = \{ P \in l : A \geq_l P \} = \{ P \in l : P \leq_l A \}
\]

is also a half-line of \( l \), with initial point \( A \). We say that \( \rho(l, A, \leq_l) \) and \( \rho(l, A, \geq_l) \) are **opposite** half-lines.

**Half-lines have the following properties:**

(i) **In all cases** \( \rho(l, A, \leq_l) \subset l \).

(ii) **In all cases** \( A \in \rho(l, A, \leq_l) \).

(iii) **If** \( B, C \in \rho(l, A, \leq_l) \), **then** \( [B, C] \subset \rho(l, A, \leq_l) \).

**Proof.**

(i) By the definition of \( \rho(l, A, \leq_l) \), we have \( P \in l \) for all \( P \in \rho(l, A, \leq_l) \) and so \( \rho(l, A, \leq_l) \subset l \).

(ii) By \( A_2 \)(i) \( A \leq_l A \), so \( A \in \rho(l, A, \leq_l) \).

(iii) As \( B, C \in \rho(l, A, \leq_l) \) we have \( A \leq_l B \) and \( A \leq_l C \). Since \( B, C \in l \), by \( A_2 \)(iv) either \( B \leq_l C \) or \( C \leq_l B \). When \( B \leq_l C \), we have \( B \leq_l P \) for all \( P \in [B, C] \); with \( A \leq_l B \) this gives \( A \leq_l P \) by \( A_2 \)(ii), and so \( P \in \rho(l, A, \leq_l) \). When \( C \leq_l B \), we have a similar proof.
2.2 OPEN AND CLOSED HALF-PLANES

2.2.1 Convex sets

**Definition.** A set \( E \) is said to be **convex** if for every \( P, Q \in E \), \( [P, Q] \subset E \) holds.

**NOTE.** By 2.1.4(iv) every segment is a convex set; by 2.1.5(iii) so is every half-line. In preparation for the next subsection, we note that by A₁, for each line \( l \in \Lambda \) we have \( \Pi \setminus l \neq \emptyset \).

2.2.2 Open half-planes

**Primitive Term.** Corresponding to each line \( l \in \Lambda \), there is a pair \( \{G_1, G_2\} \) of non-empty sets called **open half-planes** with common edge \( l \).

**Axiom A₃.** Open half-planes \( G_1, G_2 \) with common edge \( l \) have the properties:-

(i) \( \Pi \setminus l = G_1 \cup G_2 \);

(ii) \( G_1 \) and \( G_2 \) are both convex sets;

(iii) if \( P \in G_1 \) and \( Q \in G_2 \), then \( [P, Q] \cap l \neq \emptyset \).

We note the following immediately.

Open half-planes \( \{G_1, G_2\} \) with common edge \( l \) have the properties:-

(i) \( l \cap G_1 = \emptyset \), \( l \cap G_2 = \emptyset \).

(ii) \( G_1 \cap G_2 = \emptyset \).

(iii) If \( P \in G_1 \) and \( [P, Q] \cap l \neq \emptyset \) where \( Q \notin l \), then \( Q \in G_2 \).

(iv) Each line \( l \) determines a unique pair of open half-planes.

**Proof.**

(i) By A₃(i), \( l \cap (G_1 \cup G_2) = \emptyset \) and as \( G_1 \subset G_1 \cup G_2 \) it follows that \( l \cap G_1 = \emptyset \). The other assertion is proved similarly.

(ii) If \( G_1 \cap G_2 \neq \emptyset \), there is some point \( R \) in both \( G_1 \) and \( G_2 \). By A₃(iii) with \( P = R, Q = R \), we have that \( [R, R] \cap l \neq \emptyset \). But \( R \) is the only point in \( [R, R] \) so \( R \in l \). This contradicts the fact that \( l \cap G_1 = \emptyset \).

(iii) For otherwise by A₃(i), \( Q \in G_1 \) and then by A₃(ii) \( [P, Q] \subset G_1 \). As \( l \cap G_1 = \emptyset \), it follows that \( [P, Q] \cap l = \emptyset \) which contradicts the assumptions.

(iv) Suppose that

\[
\Pi \setminus l = G_1 \cup G_2 = G'_1 \cup G'_2,
\]

where \( \{G_1, G_2\} \) and \( \{G'_1, G'_2\} \) are both sets of open half-planes with common edge \( l \). Then

\[
G_1 \subset G_1 \cup G_2 = G'_1 \cup G'_2
\]

so at one of the following holds
Sec. 2.2  Open and closed half-planes

(a) \( G_1 \subset G'_1 \) or (b) \( G_1 \subset G'_2 \) or (c) \( G_1 \cap G'_1 \neq \emptyset, G_1 \cap G'_2 \neq \emptyset \).

In (c) we have \( P \in G_1, P \in G'_1 \) and \( Q \in G_1, Q \in G'_2 \) for some \( P \) and \( Q \). But then we have \( [P,Q] \subset G_1 \), by \( A_3(ii) \) applied to \( G_1 \), and \( [P,Q] \cap l \neq \emptyset \), by \( A_3(iii) \) applied to \( \{G'_1, G'_2\} \). This gives a contradiction as \( l \cap G_1 = \emptyset \). Thus (c) cannot happen.

By similar reasoning, we must have either (d) \( G'_1 \subset G_1 \) or (e) \( G'_1 \subset G_2 \).

Now (a) and (d) give \( G_1 = G'_1 \) and it follows that \( G_2 = G'_2 \).

Similarly (b) and (e) give \( G_1 = G'_2 \) and it follows that \( G_2 = G'_1 \).

Finally, we cannot have (a) and (e) as that would imply \( G_1 \subset G_2 \). Neither can we have (b) and (d).

**TERMINOLOGY.** If two points are both in \( G_1 \) or both in \( G_2 \) they are said to be on the one side of the line \( l \), while if one of the points is in \( G_1 \) and the other is in \( G_2 \) they are said to be on different sides of \( l \).

![Figure 2.5. A closed half-plane shaded.](image-url)

### 2.2.3 Closed half-planes

**Definition.** If \( G_1, G_2 \) are open half-planes with common edge \( l \), we call

\[ \mathcal{H}_1 = G_1 \cup l, \quad \mathcal{H}_2 = G_2 \cup l, \]

closed half-planes with common edge \( l \).

Closed half-planes \( \mathcal{H}_1, \mathcal{H}_2 \) with common edge \( l \) have the properties:

(i) \( \mathcal{H}_1 \cup \mathcal{H}_2 = \Pi \).

(ii) \( \mathcal{H}_1 \cap \mathcal{H}_2 = l \).

(iii) Each of \( \mathcal{H}_1, \mathcal{H}_2 \) is a convex set.

(iv) If \( A \in l \) and \( B \neq A \) is in \( \mathcal{H}_1 \), then \( [A,B] \subset \mathcal{H}_1 \).

**Proof.**

(i) By \( A_3(i) \), \( \Pi = G_1 \cup G_2 \cup l = (G_1 \cup l) \cup (G_2 \cup l) = \mathcal{H}_1 \cup \mathcal{H}_2 \).

(ii) For \( (G_1 \cup l) \cap (G_2 \cup l) = (G_1 \cap G_2) \cup (G_1 \cap l) \cup (G_2 \cap l) \cup (l \cap l) = l \cap l = l \).

(iii) We prove that \( \mathcal{H}_1 \) is convex; proof for \( \mathcal{H}_2 \) is similar.

Let \( A, B \in \mathcal{H}_1 \); we wish to show that \( [A,B] \subset \mathcal{H}_1 \).

CASE (a). Let \( A, B \in G_1 \). Then the conclusion follows from \( A_3(ii) \).
CASE (b). Let $A, B \in l$. Then $[A, B] \subset l \subset H_1$, so the result follows.

CASE (c). Let one of $A, B$ be on $l$ and the other in $G_1$, say $A \in l, B \in G_1$.

Suppose that $[A, B]$ is not a subset of $H_1$. Then there is some point $C \in [A, B]$ such that $C \notin G_2$. Note that $C \neq A, C \neq B$ as $A, B \notin G_2, C \in G_2$.

Now $B \in G_1, C \in G_2$ so by $A_3(iii)$ there is some point $D$ of $[B, C]$ on $l$, so that $D \in [B, C], D \in l$. Then $A, B, C$ are collinear and distinct, and $C \in [A, B]$ so by 2.1.4 we cannot have $A \in [B, C]$. Hence $A \neq D$.

But $A \in l, D \in l$ so by $A_1, AD = l$. However $AB = BC$ and $D \in BC$, so $D \in AB$. Then $AB = AD = l$, so $B \in l$. This gives a contradiction. Thus the original supposition is untenable so $[A, B] \subset H_1$, and this proves (iii).

(iv)

CASE (a). Let $B \in l$. Then $[A, B \subset l \subset H_1$, which gives the desired conclusion.

CASE (b). Let $B \in G_1$. Suppose that $[A, B]$ is not a subset of $H_1$. Then there is some point $C \in [A, B]$ such that $C \in G_2$. Clearly $C \neq A, C \neq B$. Now $A, B, C$ are distinct collinear points, so by 2.1.4 precisely one of

$$A \in [B, C], B \in [C, A], C \in [A, B],$$

holds. We cannot have $A \in [B, C]$ as that would put $B, C$ in different half-lines with initial-point $A$, whereas they are both in $[A, B$. This leaves us with two subcases.

Subcase 1. Let $C \in [A, B]$. We recall that $A, B \in H_1$ so by part (iii) of the present result $[A, B] \subset H_1$. As $C \in [A, B], C \in G_2$, we have a contradiction.

Subcase 2. Let $B \in [A, C]$. We recall that $A \in H_2, C \in H_2$ so by part (iii) of the present result, $[A, C] \subset H_2$. Then $B \in H_2, B \in G_1$ which gives a contradiction. Thus the original supposition is untenable, and this proves (iv).

NOTE. The terms ‘open’ and ‘closed’ are standard in analysis and point-set topology. What is significant is that an open half-plane contains none of the points of the edge, while a closed half-plane contains all of the points of the edge.

2.3 ANGLE-SUPPORTS, INTERIOR AND EXTERIOR REGIONS, ANGLES

2.3.1 Angle-supports, interior regions

Figure 2.6. An angle-support. A straight angle-support.
Definition. We call a pair \([A, B, A, C]\) of co-initial half-lines an angle-support. For this we use the notation \(|BAC|\). When \(A \in [B, C]\), this is called a straight angle-support. We call the half-lines \([A, B]\) and \([A, C]\) the arms, and the point \(A\) the vertex, of \(|BAC|\). Note that we are assuming \(B \neq A\) and \(C \neq A\) from the definition of half-lines. In all cases we have \(|BAC| = |CAB|\).

COMMENT. The reason that we do not call \(|BAC|\) an angle is that there are two angles associated with this configuration.

![Figure 2.7. An interior region.](image)

The corresponding exterior region.

Definition. Consider an angle-support \(|BAC|\) which is not straight. When \(A, B, C\) are not collinear, let \(\mathcal{H}_1\) be the closed half-plane with edge \(AB\) in which \(C\) lies, and \(\mathcal{H}_3\) the closed half-plane with edge \(AC\) in which \(B\) lies. Then \(\mathcal{H}_1 \cap \mathcal{H}_3\) is called the interior region of \(|BAC|\), and we denote it by \(\mathcal{I}(|BAC|)\). When \(A, B, C\) are collinear we have \([A, B] = [A, C]\) and we define \(\mathcal{I}(|BAC|) = [A, B]\).

Interior regions have the following properties:

(i) \([A, B]\) and \([A, C]\) are both subsets of \(\mathcal{I}(|BAC|)\).

(ii) If \(P, Q \in \mathcal{I}(|BAC|)\) then \([P, Q] \subset \mathcal{I}(|BAC|)\), so that an interior region is a convex set.

(iii) If \(P \in \mathcal{I}(|BAC|)\) and \(P \neq A\), then \([A, P] \subset \mathcal{I}(|BAC|)\).

Proof.

(i) When \(A, B, C\) are non-collinear, by 2.1.5 \([A, B] \subset AB \subset \mathcal{H}_1\) and by 2.2.3 \([A, B] \subset \mathcal{H}_3\) so \([A, B] \subset \mathcal{H}_1 \cap \mathcal{H}_3\). Similarly for \([A, C]\). When \([A, B] = [A, C]\) the result is trivial.

(ii) When \(A, B, C\) are non-collinear, we have that \([P, Q]\) is a subset of \(\mathcal{H}_1\) by 2.2.3. It is a subset of \(\mathcal{H}_3\) similarly, and so is a subset of the intersection of these closed half-planes. When \([A, B] = [A, C]\), the result follows from 2.1.5.

(iii) When \(A, B, C\) are non-collinear, by 2.2.3 \([A, P]\) is a subset of each of \(\mathcal{H}_1\) and \(\mathcal{H}_3\), and so of their intersection. When \([A, B] = [A, C]\) we have \(\mathcal{I}(|BAC|) = [A, B]\) and \([A, P] = [A, B]\).
2.3.2 Exterior regions

**Definition.** If $|BAC|$ is an angle-support which is not straight and $\mathcal{IR}(\mid BAC \mid)$ is its interior region, then
$$\{ \Pi \setminus \mathcal{IR}(\mid BAC \mid) \} \cup [A, B] \cup [A, C]$$
is called the exterior region of $|BAC|$, and denoted by $\mathcal{ER}(\mid BAC \mid)$. Thus the interior and exterior regions have in common only the arms.

2.3.3 Angles

![Figure 2.8. A wedge-angle. A reflex-angle. A straight-angle.](image)

**Definition.** Let $|BAC|$ be an angle-support which is not straight, with interior region $\mathcal{IR}(\mid BAC \mid)$ and exterior region $\mathcal{ER}(\mid BAC \mid)$. Then the pair $\left( |BAC|, \mathcal{IR}(\mid BAC \mid) \right)$ is called a **wedge-angle**, and the pair $\left( |BAC|, \mathcal{ER}(\mid BAC \mid) \right)$ is called a **reflex-angle**. If $|BAC|$ is a straight-angle support and $\mathcal{H}_1, \mathcal{H}_2$ are the closed half-planes with common edge $AB$, then each of the pairs $\left( \mid BAC \mid, \mathcal{H}_1 \right)$, $\left( \mid BAC \mid, \mathcal{H}_2 \right)$ is called a **straight-angle**.

In each case the point $A$ is called the **vertex** of the angle, the half-lines $[A, B]$ and $[A, C]$ are called the **arms** of the angle, and $|BAC|$ is called the **support** of the angle.

We denote a wedge-angle with support $|BAC|$ by $\angle BAC$. The wedge-angle $\angle BAB$ is said to be a **null-angle**. A reflex-angle with support $|BAB|$ is called a **full-angle**.

2.4 TRIANGLES AND CONVEX QUADRILATERALS

2.4.1 Terminology

**COMMENT.** The terminology which we have used hitherto is established, apart from ‘angle-support’ and ‘wedge-angle’ which we have coined. Now we are reaching terminology which is of long standing but is used in slightly varying senses.

In Euclidean geometry it is generally accepted that the concept of triangle is associated with:

(i) a set $\{A, B, C\}$ of three points which are not collinear;

(ii) a union of segments $[B, C] \cup [C, A] \cup [A, B]$, where the points $A, B, C$ are as in (i);

(iii) an intersection of half-planes $\mathcal{H}_1 \cap \mathcal{H}_3 \cap \mathcal{H}_5$, where $A, B, C$ are as in (i), $\mathcal{H}_1$ is the closed half-plane with edge $BC$ in which $A$ lies, $\mathcal{H}_3$ is the closed half-plane...
with edge $CA$ in which $B$ lies, and $\mathcal{H}_3$ is the closed half-plane with edge $AB$ in which $C$ lies.

However in some courses the actual definition of a triangle is taken to be (i), in other courses it is taken to be (ii), and in other courses it is taken to be (iii), with (ii) and (iii) very common. In yet other courses a combination of (i) and (ii) is taken.

Having to make a choice for the sake of precision, we opt for (iii); then for us (i) will be the set of vertices of our triangle, and (ii) will be the perimeter of our triangle, with the individual segments being the sides. We shall then be able to refer naturally to the area of a triangle and the length of its perimeter.

Consideration similar to (i), (ii) and (iii) for a triangle surround each of the terms quadrilateral, parallelogram, rectangle and square, and we adopt our terminology consistently.

### 2.4.2 Triangles

**NOTE.** Let $A, B, C$ be points which do not lie on one line. Then by $A_1$, $A, B, C$ are distinct points, and $A \notin BC$, $B \notin CA$, $C \notin AB$. In fact these lines are not concurrent; for $BC$ and $CA$ cannot have a point $P$ in common other than $P = C$, while $C \notin AB$.

**Definition.** For non-collinear points $A, B, C$ let $\mathcal{H}_1$ be the closed half-plane with edge $BC$ in which $A$ lies, $\mathcal{H}_3$ the closed half-plane with edge $CA$ in which $B$ lies, and $\mathcal{H}_5$ the closed half-plane with edge $AB$ in which $C$ lies. Then the intersection $\mathcal{H}_1 \cap \mathcal{H}_3 \cap \mathcal{H}_5$ is called a **triangle**, and is denoted by $[A, B, C]$.

![Figure 2.9. A triangle $[A, B, C]$.](image1)

![Figure 2.10. A convex quadrilateral.](image2)

The points $A, B, C$ are called its **vertices**; the segments $[B, C], [C, A], [A, B]$ are called its **sides**; the lines $BC, CA, AB$ are called its **side-lines**. The union $[B, C] \cup [C, A] \cup [A, B]$ of its sides is called its **perimeter**. A side and a vertex not contained in it are said to be **opposite**; thus $A$ is opposite $[B, C]$ but is not opposite $[C, A]$ or $[A, B]$.

**Triangles have the following properties:**-

(i) $[A, B, C]$ is independent of the order of the points $A, B, C$.

(ii) Each of the vertices $A, B, C$ is an element of $[A, B, C]$.

(iii) If $P, Q \in [A, B, C]$, then $[P, Q] \subset [A, B, C]$ so that a triangle is a convex set.
(iv) Each of the sides \([B,C],[C,A],[A,B]\) is a subset of \([A,B,C]\).

**Proof.** (i) As \(\cap\) is commutative, \(\mathcal{H}_1 \cap \mathcal{H}_3 \cap \mathcal{H}_5\) is independent of the order of \(\mathcal{H}_1, \mathcal{H}_3, \mathcal{H}_5\).

(ii) The vertex \(A\) is in \(\mathcal{H}_1\) by definition. It is also in the edge of each of \(\mathcal{H}_3\) and \(\mathcal{H}_5\), so by 2.2.3 it is in each of these closed half-planes. The vertices \(B\) and \(C\) are treated similarly.

(iii) By definition of an intersection, \(P\) and \(Q\) are in each of \(\mathcal{H}_1, \mathcal{H}_3, \mathcal{H}_5\). By 2.2.3, \([P,Q]\) is a subset of each of these closed half-planes, and so it is a subset of their intersection.

(iv) This follows from parts (ii) and (iii) of the present result.

### 2.4.3 Pasch’s property, 1882

**Pasch’s property.** If a line cuts one side of a triangle, not at a vertex, then it will either pass through the opposite vertex, or cut one of the other two sides.

**Proof.** Let \([A,B,C]\) be the triangle and \(l\) a line which cuts the side \([A,B]\) at a point which is not a vertex. If \(C \in l\) we have the first conclusion. Otherwise suppose that \(l\) does not cut \([B,C]\). Then \(A\) and \(B\) are on different sides of \(l\), but \(B\) and \(C\) are on the same side of \(l\). It follows that \(A\) and \(C\) are on different sides if \(l\), so by \(A_3 (iii)\) a point of \([A,C]\) lies on \(l\).

### 2.4.4 Convex quadrilaterals

**Definition.** Let \(A, B, C, D\) be four points in \(\Pi\), no three of which are collinear, and such that \([A,C] \cap [B,D] \neq \emptyset\). Let \(\mathcal{H}_1\) be the closed half-plane with edge \(AB\) in which \(D\) lies, \(\mathcal{H}_3\) the closed half-plane with edge \(BC\) in which \(A\) lies, \(\mathcal{H}_5\) the closed half-plane with edge \(CD\) in which \(B\) lies, and \(\mathcal{H}_7\) the closed half-plane with edge \(DA\) in which \(C\) lies. Then the intersection \(\mathcal{H}_1 \cap \mathcal{H}_3 \cap \mathcal{H}_5 \cap \mathcal{H}_7\) of these four half-planes is called a convex quadrilateral, and we denote it by \([A,B,C,D]\). As each of the closed half-planes is a convex set this intersection is also a convex set.

Each of the four points \(A,B,C,D\) is called a vertex; the segments \([A,B], [B,C], [C,D], [D,A]\) are called the sides; and \(AB, BC, CD, DA\) are called the side-lines; the union of the sides \([A,B] \cup [B,C] \cup [C,D] \cup [D,A]\) is called the perimeter. The segments \([A,C], [B,D]\) are called the diagonals, and \(AC, BD\) the diagonal lines. Vertices which are the end-points of a side are called adjacent while vertices which are the end-points of a diagonal are called opposite; thus \(A\) and \(B\) are adjacent as \([A,B]\) is a side, and \(A\) and \(C\) are opposite as \([A,C]\) is a diagonal. Sides which have a vertex in common are said to be adjacent while sides which do not have a vertex in common are said to be opposite; thus the sides \([A,B], [A,D]\) are adjacent as the vertex \(A\) is in both, while the sides \([A,B], [C,D]\) are opposite as neither \(C\) nor \(D\) is in \(AB\) and so neither of them could be \(A\) or \(B\).
If we write

\[
\begin{array}{c}
D \\
/ \\
/ \\
A & C \\
/ \\
/ \\
B
\end{array}
\]

then two vertices in \([A,B,C,D]\) will be adjacent if the letters for them in this diagram are linked.

**Exercises**

2.1 Let \(P\) be a fixed point in \(\Pi\). Identify the union of all lines \(l \in \Lambda\) such that \(P \in l\).

2.2 Prove that segments have the following properties:-

(i) If \(C \in [A,B]\), then \([A,C] \cup [C,B] = [A,B]\) and \([A,C] \cap [C,B] = \{C\}\).

(ii) If \(C \in [A,B]\) and \(B \in [A,C]\) then \(B = C\).

(iii) If \(C \in [A,B]\) and \(D \in [A,C]\), then \(C \in [D,B]\).

(iv) If \(B \neq A\), \(B \in [A,C]\) and \(B \in [A,D]\), then either \(C \in [B,D]\) or \(D \in [B,C]\).

2.3 Prove that half-lines have the following properties:-

(i) If \(B \in \rho(l, A, \leq t)\), then \(\rho(l, B, \leq t) \subset \rho(l, A, \leq t)\).

(ii) If \(B \in \rho(l, A, \leq t)\), then \(\rho(l, A, \leq t) = [A,B] \cup \rho(l, B, \leq t)\) and \([A,B] \cap \rho(l, B, \leq t) = \{B\}\).

(iii) Let \(B \in \rho(l, A, \leq t)\), \(A \neq B\) and \(A \in [B,C]\). Then \(C \in \rho(l, A, \leq t)\) only if \(C = A\).

(iv) Let \(B \in \rho(l, A, \leq t)\) and \(A \neq B\). Then \(C \in \rho(l, A, \leq t)\) if and only if either \(B \in [A,C]\) or \(C \in [A,B]\).

(v) In all cases

\[
\rho(l, A, \leq t) \cup \rho(l, A, \geq t) = l \text{ and } \rho(l, A, \leq t) \cap \rho(l, A, \geq t) = \{A\}.
\]

(vi) Let \(B \in \rho(l, A, \leq t)\) and \(A \neq B\). Then \(C \in \rho(l, A, \geq t)\) if and only if \(A \in [B,C]\).

(vii) Let \(B \in \rho(l, A, \leq t)\) and \(A \neq B\). Then

\[
\rho(l, A, \leq t) \cup \rho(l, B, \geq t) = l, \quad \rho(l, A, \leq t) \cap \rho(l, B, \geq t) = [A,B],
\]

\[
\rho(l, A, \geq t) \cap \rho(l, B, \leq t) = \emptyset, \quad \rho(l, A, \geq t) \cup \rho(l, B, \leq t) \cup [A,B] = l.
\]

(viii) If \(A \neq B, A \neq C\) and \(C \in [A,B]\), then \([A,B] = [A,C]\).
2.4 If \([A, B], [C, D]\) are both segments of a line \(l\) such that \([A, B] \cap [C, D] \neq \emptyset\), show that \([A, B] \cap [C, D]\) and \([A, B] \cup [C, D]\) are both segments.

2.5 Show that if \(A \neq B\) and \(C, D\) are both in \(AB \setminus [A, B]\), then either \([A, B] \cap [C, D] = \emptyset\) or \([A, B] \subset [C, D]\).

2.6 Let \(\leq_E\) be a total order on the set \(E\) and \(f : E \to F\) a 1:1 onto function. If for \(a, b \in F, a \leq_F b\) when \(f^{-1}(a) \leq_E f^{-1}(b)\), show that \(\leq_F\) is a total order on \(F\).

2.7 Use Ex.2.6 to show that if \(F\) is an infinite set and there is a total order on \(F\), then there are infinitely many total orders on \(F\).

2.8 Show that interior regions have the following properties:-

(i) If \(P \in \mathcal{IR}([AB])\) and \(P \neq A\), then \(AP \cap \mathcal{IR}([AB]) = [A, P]\).
(ii) If \(A, B, C\) are non-collinear and \(U \in [A, B]\), \(V \in [A, C]\) but neither \(U\) nor \(V\) is \(A\), then \(UV \cap \mathcal{IR}([BC]) = [U, V]\).

(iii) If \(A, U, V\) are distinct collinear points, and \(U\) and \(V\) are both in \(\mathcal{IR}([BC])\), then \(V \in [A, U]\).

2.9 Show that an exterior region has the following properties:-

(i) The arms \([A, B]\) and \([A, C]\) are both subsets of \(\mathcal{ER}([BC])\).
(ii) If \(P \in \mathcal{ER}([BC])\) and \(P \neq A\), then \([A, P] \subset \mathcal{ER}([BC])\).

2.10 Show that convex quadrilaterals \([A, B, C, D]\) have the following properties:-

(i) Each of

\[
\langle 2 \rangle [A, D, C, B], \quad \langle 3 \rangle [C, B, A, D], \quad \langle 4 \rangle [C, D, A, B],
\]

\[
\langle 5 \rangle [B, A, D, C], \quad \langle 6 \rangle [B, C, D, A], \quad \langle 7 \rangle [D, A, B, C],
\]

\[
\langle 8 \rangle [D, C, B, A],
\]

is equal to \(\langle 1 \rangle [A, B, C, D]\).

(ii) Each of the vertices \(A, B, C, D\) is an element of \([A, B, C, D]\).

(iii) The lines \(AC\) and \(BD\) cannot have distinct points \(E\) and \(F\) in common.

(iv) Each side and each diagonal is a subset of \([A, B, C, D]\).

(v) Any pair of opposite sides are disjoint.

2.11 For non-collinear points \(A, B, D\) let \(C\) be a point which is in the interior region \(\mathcal{IR}([BAD])\) but not in \([A, B] \cup [A, D]\) or \([A, B, D]\). Show that then \(A, B, C, D\) are the vertices of a convex quadrilateral.
Distance; degree-measure of an angle

COMMENT. In this chapter we introduce distance as a primitive concept, relate it to the properties of segments, and define the notion of the mid-point of two points. We also introduce as a primitive concept the notion of the degree-measure of a wedge-angle and of a straight-angle, relate it to the properties of interior-regions and half-planes, and define the notion of the mid-line of an angle-support.

3.1 DISTANCE

3.1.1 Axiom for distance

Notation. We denote by \( \mathbb{R} \) the set of real numbers.

Primitive Term. There is a function \( | | : \Pi \times \Pi \to \mathbb{R} \) called distance. We read \( |A,B| \) as the distance from \( A \) to \( B \). We also refer to \( |A,B| \) as the length of the segment \([A,B]\).

AXIOM A_{4}. Distance has the following properties:

(i) \( |A,B| \geq 0 \) for all \( A,B \in \Pi \);

(ii) \( |A,B| = |B,A| \) for all \( A,B \in \Pi \);

(iii) If \( Q \in [P,R] \), then \( |P,Q| + |Q,R| = |P,R| \);

(iv) Given any \( k \geq 0 \) in \( \mathbb{R} \), any line \( l \in \Lambda \), any point \( A \in l \) and either natural order \( \leq_l \) on \( l \), there is a unique point \( B \in l \) such that \( A \leq_l B \) and \( |A,B| = k \), and a unique point \( C \in l \) such that \( C \leq_l A \) and \( |A,C| = k \).

COMMENT. Note that A_{4}(iv) states that we can lay off a distance \( k \), uniquely, on \( l \) on either side of \( A \). The fact that different letters \( A,B,C \) are used is not to be taken as a claim that \( A,B,C \) are distinct in all cases. Axiom A_{4}(iv) implies that each line \( l \)
contains infinitely many points and this supersedes the specification in A₁ that \( l \neq \emptyset \); nevertheless it was convenient to stipulate the latter to avoid a trivial situation. In A₄(iii) addition \(+\) of real numbers is involved.

![Figure 3.1. Addition of distances.](image)

**3.1.2 Derived properties of distance**

*Distance has the following properties:-*

(i) For all \( A \in \Pi \) \(|A,A| = 0\), and we have \(|A,B| > 0\) if \( A \neq B \).

(ii) If \( P \in [A,B] \), then \(|A,P| \leq |A,B|\). If additionally \( P \neq B \), then \(|A,P| < |A,B|\).

(iii) If \( A \neq C \) and \( B \) lies on the line \( AC \) but outside the segment \([A,C]\), then

\[ |A,B| + |B,C| > |A,C|. \]

(iv) If \( C \in [A,B] \) is such that \(|A,B| < |A,C|\), then \( B \in [A,C] \).

**Proof.**

(i) By A₄(iii) with \( P = Q = A \) and any \( R \in \Pi \), we have \(|A,A| + |A,R| = |A,R|\), i.e. \( x + y = y \) where \( x = |A,A| \) and \( y = |A,R| \). It follows that \( x = 0 \).

Next with \( A \neq B \) let \( l = AB \) and \( \leq_l \) be the natural order on \( l \) for which \( A \leq_l B \). Then we have

\[ A \leq_l B, A \leq_l A, |A,A| = 0, \]

so that if we also had \(|A,B| = 0\), then by the uniqueness part of A₄(iv) with \( k = 0 \), we would have \( A = B \) and so have a contradiction. To avoid this we must have \(|A,B| > 0\).

(ii) As \( P \in [A,B] \), by A₄(iii) we have \(|A,P| + |P,B| = |A,B|\). But by A₄(i) \(|P,B| \geq 0\) and so \(|A,P| \leq |A,B|\). If \( P \neq B \), then by (i) of the present theorem \(|P,B| > 0\) and so \(|A,P| < |A,B|\).

(iii) As \( B \not\in [A,C] \) we have \( B \neq A, B \neq C \) and so by 2.1.4 we have either \( A \in [B,C] \) or \( C \in [A,B] \). In the first of these \(|B,A| + |A,C| = |B,C|\) by A₄(iii) and as \(|A,B| = |B,A| > 0\) this gives \(|A,C| < |B,C| < |A,B| + |B,C|\). In the second case we have \(|A,C| + |C,B| = |A,B|\) by A₄(iii) and as \(|C,B| = |B,C| > 0\), then \(|A,C| < |A,B| < |A,B| + |B,C|\).
(iv) We have \( A \neq B \) by definition of \([A, B]\), and \( A \neq C \) as \( 0 < |A, B| < |A, C| \) so that \( 0 < |A, C| \). We also have \( B \neq C \) as \( |A, B| < |A, C| \) combined with \( B = C \) would give \( |A, B| < |A, B| \), whereas once \((A, B)\) is known \( |A, B| \) is uniquely determined. We cannot have \( A \in [B, C] \) as \( C \in [A, B] \). Then by 2.1.4 either \( B \in [C, A] \) or \( C \in [A, B] \). But by (ii) of the present result, if \( C \in [A, B] \) we would have \( |A, C| \leq |A, B| \). As this is ruled out by assumption, we must have \( B \in [A, C] \).

Segments and half-lines have the following further properties:-

(i) Let \( l \in \Lambda \) be a line, \( A \in l \) and \( \leq_l \) a natural order on \( l \). Then there are points \( B \) and \( C \) on \( l \) such that \( A \leq_l B \) and \( B \neq A \), and such that \( C \leq_l A \) and \( C \neq A \).

(ii) If \( A \neq B \), there are points \( X \in [A, B] \) such that \( X \neq A \) and \( X \neq B \).

(iii) If \( [A, B] = [C, D] \) then \( A = C \).

![Figure 3.2](image)

**Proof.**

(i) By \( A_4 \)(iv) with any \( k > 0 \), there is some \( B \in l \) such that \( A \leq_l B \) and \(|A, B| = k\). As \(|A, B| > 0\), we have \( A \neq B \). Proof for the existence of \( C \) is similar.

(ii) Let \( \leq_l \) be the natural order on \( l = AB \) for which \( A \leq_l B \). As \( A \neq B \) we have \(|A, B| > 0 \) and then with any \( k \) such that \( 0 < k < |A, B| \), there is a point \( X \in l \) such that \( A \leq_l X \) and \(|A, X| = k\). As \(|A, X| \neq 0\), we have \( A \neq X \); as \(|A, X| < |A, B| \) then \( X \neq B \). As \( X \in [A, B] \) and \(|A, X| < |A, B| \), we have \( X \in [A, B] \).

(iii) With the notation of (ii), \( P \in [A, B] \) if and only if \( A \leq_l P \). Now \( C \in [C, D] = [A, B] \) so \( A \leq_l C \); similarly \( A \leq_l D \).

**CASE 1.** Let \( C \leq_l D \), so that \([C, D] = \{Q \in l : C \leq_l Q\}\). As \( A \in [A, B] = [C, D] \) we have \( C \leq_l A \) and this combined with \( A \leq_l C \) implies \( A = C \).

**CASE 2.** Let \( D \leq_l C \). Then \([C, D] = \{Q \in l : Q \leq_l C\}\). By (i) of the present result there is an \( X \in l \) such that \( X \leq_l A \) and \( X \neq A \). Then \( X \leq_l A, A \leq_l C \) so \( X \leq_l C \) and thus \( X \in [C, D] \). However \( X \notin [A, B] \) as otherwise we would have \( A \leq_l X \) which combined with \( X \leq_l A \) implies \( X = A \) and involves a contradiction. Then \( X \in [C, D], X \notin [A, B] \) which contradicts the fact that \([A, B] = [C, D] \) and so this case cannot occur.
3.2 MID-POINTS

3.2.1

If \( A \neq B \) there is a unique point \( X \) on \( l = AB \) such that \( |A,X| = |X,B| \). In this in fact \( X \in [A,B] \) and \( X \neq A, X \neq B \).

Proof.

Existence. Let \( \leq \) be the natural order on \( l \) for which \( A \leq B \). With \( k = \frac{1}{2}|A,B| \), by A4(iv) there is a point \( X \) on \( l \) such that \( A \leq X \) and \( |A,X| = \frac{1}{2}|A,B| \). Clearly \( X \in [A,B] \).

As \( |A,B| > 0 \) we have \( |A,X| < |A,B| \); by 3.1.2 this implies that \( X \in [A,B], X \neq B \). By A4(iii) \( |A,X| + |X,B| = |A,B| \) and so \( |X,B| = |A,B| - \frac{1}{2}|A,B| = \frac{1}{2}|A,B| \). Thus \( |A,X| = |X,B| \) as required. We have already seen that \( X \in [A,B] \) and \( X \neq B \); as \( |A,X| > 0 \) we also have \( X \neq A \).

Uniqueness. Suppose now that \( Y \in l \) and \( |A,Y| = |Y,B| \). Then \( Y \) cannot be \( A \) or \( B \), as e.g. \( Y = A \) implies that \( |A,A| = |A,B| \), i.e. \( 0 = |A,B| \). Thus by 2.1.4 one of

\[
Y \in [A,B], \ A \in [Y,B], \ B \in [A,Y],
\]

holds. The second of these would imply \( |Y,A| + |A,B| = |Y,B| \) and so \( |Y,A| < |Y,B| \) as \( |A,B| > 0 \). The third of these would imply \( |A,B| + |B,Y| = |A,Y| \) and so \( |B,Y| < |A,Y| \). As these contradict our assumptions, we must have \( Y \in [A,B] \). Then \( |A,Y| + |Y,B| = |A,B| \) and as \( |A,Y| = |Y,B| \) this implies that \( |A,Y| = \frac{1}{2}|A,B| \). Then \( A \leq l X, A \leq l Y \) and \( |A,X| = |A,Y| \) so by the uniqueness in A4(iv) we must have \( X = Y \).

Definition. Given any points \( A, B \in \Pi \), we define the mid-point of \( A \) and \( B \) as follows: if \( A = B \) then the mid-point is \( A \); when \( A \neq B \) the mid-point is the unique point \( X \) on the line \( AB \) such that \( |A,X| = |X,B| \), which has just been guaranteed. We denote the mid-point of \( A \) and \( B \) by \( \text{mp}(A,B) \).

Mid-points have the following properties:-

(i) For all \( A, B \in \Pi \), \( \text{mp}(A,B) = \text{mp}(B,A) \).
(ii) For all $A, B \in \Pi$, $\text{mp}(A, B) \in [A, B]$.

(iii) In all cases $\text{mp}(A, A) = A$, and $\text{mp}(A, B) \neq A, \text{mp}(A, B) \neq B$ when $A \neq B$.

(iv) Given any points $P$ and $Q$ in $\Pi$, there is a unique point $R \in \Pi$ such that $Q = \text{mp}(P, R)$.

**Proof.**

(i) When $A \neq B$ this follows from the definition and A4(ii); when $A = B$ it is immediate.

(ii) When $A \neq B$ this follows from the preparatory result. When $A = B$ it amounts to $A \in \{A\}$.

(iii) This follows from the definition and preparatory result.

(iv) Existence. If $Q = P$ we take $R = P$ and then $\text{mp}(P, R) = \text{mp}(P, P) = P = Q$. Suppose then that $P \neq Q$, let $l = PQ$ and let $\leq$ be the natural order on $l$ under which $P \leq Q$. Take $R$ on $l$ so that $P \leq R$ and $|P, R| = 2|P, Q|$. Then $P$ precedes both $Q$ and $R$ on $l$, while $|P, Q| = \frac{1}{2}|P, R|$. By our initial specification of $X$ in the preparatory result we see that $Q = \text{mp}(P, R)$.

Uniqueness. Suppose that also $Q = \text{mp}(P, S)$. We again first take $Q = P$. Now in the preparatory result we had $X \neq A$, so that cannot be the situation here as $Q = P$; thus we must have $S = P$ and so $S = R$. Next suppose that $Q \neq P$; then we cannot have $S = P$, as we had $X \neq A$. Then $Q \in PS$, so by $A_1$ $S \in PQ$. In fact $Q \in [P, S]$ so as $P \leq Q$ we must have $P \leq S$; moreover $|P, R| = |P, S|$ as each is twice the distance $|P, Q|$. By the uniqueness in A4(iv) we must then have $R = S$.

### 3.3 A RATIO RESULT

#### 3.3.1

Let $A, B, C$ be distinct collinear points, and write

$$\frac{|A, C|}{|A, B|} = r, \frac{|A, C|}{|C, B|} = s.$$ 

Then if $C \in [A, B]$ we have

$$s = \frac{r}{1 - r}, \quad r = \frac{s}{1 + s}.$$ 

**Proof.** Let $|A, C| = x$, $|C, B| = y$. As $C \in [A, B]$ we have $|A, B| = x + y$. Then

$$\frac{x}{x + y} = r \quad \text{so that} \quad \frac{x + y}{x} = \frac{1}{r}.$$ 

Hence

$$\frac{y}{x} = \frac{1}{r} - 1 \quad \text{and so} \quad \frac{x}{y} = \frac{|A, C|}{|C, B|} = \frac{r}{1 - r}.$$
In turn
\[ s = \frac{r}{1 - r} \quad \text{and so} \quad s - sr = r, \]
giving
\[ s = r(1 + s) \quad \text{and thus} \quad r = \frac{s}{1 + s}. \]

### 3.4 THE CROSS-BAR THEOREM

#### 3.4.1

**The cross-bar theorem.** Let \( A, B, C \) be non-collinear points, \( X \neq A \) any point on \([A, B]\) and \( Y \neq A \) any point on \([A, C]\). If \( D \neq A \) is any point in the interior region \( \mathcal{R}(\angle BAC) \), then \([A, D] \cap [X, Y] \neq \emptyset \).

**Proof.** If \( D \) is on \([A, B] \) or \([A, C] \) the result is clear, so we turn to other cases. By 3.1.2 there is a point \( E \neq A \) such that \( A \in [E, X] \). Thus \( X \) and \( E \) are on different sides of the line \( AC \).

Then by 2.2.3(iv) every point of \([Y, E] \) (other than \( Y \)) is on one side of \( AC \), while every point of \([A, D] \) (other than \( A \)) is on a different side of \( AC \); thus \([A, D] \) does not meet \([Y, E] \). Moreover the other points of the line \( AD \) are on one side of the line \( AB \), while the points of \([E, Y] \) (other than \( E \)) are on the other side of \( AB \). On combining these two, we see that the line \( AD \) does not meet the side \([E, Y] \) of the triangle \([E, X, Y] \). As \( AD \) does meet the side \([E, X] \) of that triangle, we see by 2.4.3 that \( AD \) must meet the third side \([X, Y] \) of that triangle at some point \( F \). As \( F \in [X, Y] \subset \mathcal{R}(\angle BAC) \), \( F \) must be on the part of \( AD \) in \( \mathcal{R}(\angle BAC) \), that is \( F \in [A, D] \).

### 3.5 DEGREE-MEASURE OF ANGLES

#### 3.5.1 Axiom for degree-measure

**Primitive Term.** There is a function \( |\cdot|^{\circ} \) on the set of all wedge-angles and straight-angles, into \( \mathbb{R} \). Thus with each angle \( \alpha \), either a wedge-angle \( \alpha = \angle BAC \) or a straight-angle with support \( BAC \), there is associated a unique real number \( |\alpha|^{\circ} \), called its degree-measure.
AXIOM A5. Degree-measure | ° of angles has the following properties:

(i) In all cases |α|° ≥ 0;

(ii) If α is a straight-angle, then |α|° = 180;

(iii) If ∠BAC is a wedge-angle and the point D ≠ A lies in the interior region \(I\mathcal{R}(\angle BAC)\), then

\[|\angle BAD|° + |\angle DAC|° = |\angle BAC|°,\]

while if |BAC is a straight angle-support and D ∉ AB, then

\[|\angle BAD|° + |\angle DAC|° = 180;\]

(iv) If B ≠ A, if \(\mathcal{H}_1\) is a closed half-plane with edge AB and if the half-lines \([A,C\) and \([A,D\) in \(\mathcal{H}_1\) are such that |∠BAC|° = |∠BAD|°, then \([A,D = [A,C\);

(v) If B ≠ A, if \(\mathcal{H}_1\) is a closed half-plane with edge AB and if 0 < k < 180, then there is a half-line \([A,C\) in \(\mathcal{H}_1\) such that |∠BAC|° = k.]

COMMENT. The properties and proofs for degree-measure are quite like those for distance, with the role of interior regions analogous to that of segments. We note that A5(i) is like A4(i), A5(iii) is like A4(iii), A5(iv) is like the uniqueness part of A4(iv) and A5(v) is like the existence part of A4(iv). Wedge-angles ∠BAD and ∠DAC such as those in the second part of A5(iii) are said to be supplementary

3.5.2 Derived properties of degree-measure

Definition. For a wedge-angle ∠BAC, if we take a point \(B_1 ≠ A\) so that \(A ∈ [B,B_1]\) and a point \(C_1 ≠ A\) so that \(A ∈ [C,C_1]\), then ∠B1AC1 is called the vertically opposite angle of ∠BAC.
Degree-measure has the properties:-

(i) The null-angle \( \angle BAB \) has degree-measure 0.

(ii) For any non-null wedge-angle \( \angle BAC \), we have \( 0 < |\angle BAC|^\circ < 180 \).

(iii) If \( \angle B_1AC_1 \) is the angle vertically opposite to \( \angle BAC \), then

\[ |\angle B_1AC_1|^\circ = |\angle BAC|^\circ, \]

so that vertically opposite angles have equal degree-measures.

Proof.

(i) Let \( C \) be a point not on \( AB \). Then by A5(iii) with \( D = B \),

\[ |\angle BAB|^\circ + |\angle BAC|^\circ = |\angle BAC|^\circ. \]

It follows that \( |\angle BAB|^\circ = 0 \).

(ii) Given any non-null wedge-angle \( \angle BAC \), let \( \mathcal{H}_1 \) be the closed half-plane with edge \( AB \) in which \( C \) lies. If we had \( |\angle BAC|^\circ = 0 \), then we would have \( |\angle BAC|^\circ = |\angle BAB|^\circ \) and so by A5(iv) we would have \( [A, C] = [A, B] \). This would imply that \( \angle BAC \) is null, contrary to assumption. Then by A5(i) \( |\angle BAC|^\circ > 0 \).

Now choose the point \( E \neq A \) so that \( A \in [B, E] \). Then by A5(iii), as we have supplementary angles,

\[ |\angle BAC|^\circ + |\angle CAE|^\circ = 180. \]

But \( [A, E] \neq [A, C] \) as \( \angle BAC \) is a wedge-angle, so \( \angle CAE \) is not a null-angle. By the last paragraph we then have \( |\angle CAE|^\circ > 0 \) and it follows that \( |\angle BAC|^\circ < 180 \).

(iii) As \([BAB_1], [CAC_1]\) are straight we have

\[ |\angle BAC|^\circ + |\angle CAB_1|^\circ = 180, \]
\[ |\angle CAB_1|^\circ + |\angle B_1AC_1|^\circ = 180, \]

there being two pairs of supplementary angles. It follows that

\[ |\angle BAC|^\circ + |\angle CAB_1|^\circ = |\angle CAB_1|^\circ + |\angle B_1AC_1|^\circ, \]

from which we conclude by subtraction that \( |\angle BAC|^\circ = |\angle B_1AC_1|^\circ \).
Degree-measure has the further properties:

(i) If \( \angle BAC \) is a wedge-angle and \( D \neq A \) is in \( IR(\|BAC\|) \), then \( |\angle BAD| \leq |\angle BAC| \). If, further, \( D \notin [A,C] \) then \( |\angle BAD| < |\angle BAC| \).

(ii) For non-collinear points \( A,B,C \) let \( \mathcal{H}_1 \) be the closed half-plane with edge \( AB \) in which \( C \) lies. If \( D \neq A \) is in \( \mathcal{H}_1 \) and \( |\angle BAD| \leq |\angle BAC| \), then \( D \in IR(\|BAC\|) \).

![Figure 3.9.](image)

**Proof.**

(i) As \( D \in IR(\|BAC\|) \), by \( A_5(iii) \) \( |\angle BAD| \leq |\angle BAC| \). By \( A_5(i) \), \( |\angle DAC| \geq 0 \) so \( |\angle BAD| \leq |\angle BAC| \).

If \( D \notin [A,C] \) then \( \angle DAC \) is not a null-angle, so \( |\angle DAC| > 0 \) and hence \( |\angle BAD| < |\angle BAC| \).

(ii) Let \( E \neq A \) be such that \( A \in [B,E] \). Let \( \mathcal{H}_3, \mathcal{H}_4 \) be the closed half-planes with common edge \( AC \), with \( B \in \mathcal{H}_3 \) and \( E \in \mathcal{H}_4 \). Then

\[
\mathcal{H}_1 = \mathcal{H}_1 \cap \Pi = \mathcal{H}_1 \cap (\mathcal{H}_3 \cup \mathcal{H}_4) = (\mathcal{H}_1 \cap \mathcal{H}_3) \cup (\mathcal{H}_1 \cap \mathcal{H}_4) = IR(\|BAC\|) \cup IR(\|EAC\|).
\]

As \( D \in \mathcal{H}_1 \), then either \( D \in IR(\|BAC\|) \) or \( D \in IR(\|EAC\|) \).

Now suppose that \( D \notin IR(\|BAC\|) \), so that \( D \in IR(\|EAC\|) \) and \( D \notin [A,C] \). By \( A_5(iii) \),

\[
|\angle EAD| + |\angle DAC| = |\angle EAC|.
\]

Hence by \( A_5(iii) \), as we have supplementary pairs of angles,

\[
180 - |\angle BAD| + |\angle DAC| = 180 - |\angle BAC|.
\]

From this

\[
|\angle BAC| + |\angle DAC| = |\angle BAD|,\]

and as \( |\angle DAC| > 0 \), we have \( |\angle BAC| < |\angle BAD| \). This gives a contradiction with our hypothesis.
3.6 MID-LINE OF AN ANGLE-SUPPORT

3.6.1 Right-angles

Definition. Given any point \( P \neq A \) of a line \( AB \), by \( A_5(v) \) there is a half-line \([P,Q]\) such that \( \angle APQ = 90 \). Then \( \angle APQ \) is called a right-angle.

If \( R \neq P \) is such that \( P \in [A,R] \) then \( \angle RPQ \) is also a right-angle. For \( |APR| \) is a straight angle-support, so having supplementary angles,

\[
\angle APQ + \angle QPR = 180.
\]

As \( \angle APQ = 90 \) it follows that \( \angle RPQ = 180 - 90 = 90 \).

3.6.2 Perpendicular lines

Definition. If \( l, m \) are lines in \( \Lambda \), we say that \( l \) is perpendicular to \( m \), written \( l \perp m \), if \( l \) meets \( m \) at some point \( P \) and if \( A \neq P \) is on \( l \), and \( Q \neq P \) is on \( m \), then \( \angle APQ \) is a right-angle.

COMMENT. In 3.6.1, we say that a perpendicular \( PQ \) has been erected to the line \( AB \) at the point \( P \) on it.

Perpendicularity has the following properties:-

(i) If \( l \perp m \), then \( m \perp l \).

(ii) If \( l \perp m \), then \( l \neq m \) and \( l \cap m \neq \emptyset \).

Proof.
These follow immediately from the definition of perpendicularity.
3.6.3 Mid-lines

Given any angle-support $\overline{BAC}$ such that $C \notin [A,B]$, there is a unique line $l$ such that $A \in l$ and for all $P \neq A$ but $P \in l$, $\angle BAP^\circ = \angle PAC^\circ$.

**Proof.**

Existence.

This was already shown in 3.6.1 in the case when $\overline{BAC}$ is straight, so we may assume that $A,B,C$ are non-collinear.

By $A_5(v)$ and 3.5.2, as $0 < \angle BAC^\circ < 180$ and so $0 < \frac{1}{2} \angle BAC^\circ < 90$, there is a half-line $\overline{AP}$ with $P$ on the same side of $\overline{AB}$ as $C$ is, such that $\angle BAP^\circ = \frac{1}{2} \angle BAC^\circ$.

Then $\overline{AP} \subset IR(\overline{BAC})$ by 3.5.2, so by $A_5(iii)$

$$\angle BAP^\circ + \angle PAC^\circ = \angle BAC^\circ.$$

![Figure 3.11](image)

It follows that

$$\angle PAC^\circ = \angle BAC^\circ - \frac{1}{2} \angle BAC^\circ = \frac{1}{2} \angle BAC^\circ$$

and so $\angle BAP^\circ = \angle PAC^\circ$.

If $P' \neq A$ is such that $A \in [P,P']$, then by $A_5(iii)$

$$\angle BAP'^\circ = 180 - \angle BAP^\circ = 180 - \angle PAC^\circ = \angle P'AC^\circ.$$

Uniqueness.

When $\overline{BAC}$ is straight, by $A_5(iii)$ $2\angle BAP^\circ = 180$ so $\angle BAP^\circ = 90$. By $A_5(iv)$ this determines $l$ uniquely. For the remainder we suppose then that we have a wedge-angle $\overline{BAC}$.

Let $\mathcal{H}_1, \mathcal{H}_2$ be the closed half-planes with common edge $AB$, with $C \in \mathcal{H}_1$, and $\mathcal{H}_3, \mathcal{H}_4$ be the closed half-planes with common edge $AC$, with $B \in \mathcal{H}_3$. Let $B_1 \neq A$ be such that $A \in [B,B_1]$.

Now if $l$ contains a point $Q \neq A$ in $\mathcal{H}_4$ it will also contain a point $R \neq A$ of $\mathcal{H}_3$, so we may assume that $l$ contains a point $P \neq A$ of $\mathcal{H}_3$. As

$$\mathcal{H}_1 = \mathcal{H}_1 \cap \Pi = \mathcal{H}_1 \cap (\mathcal{H}_3 \cup \mathcal{H}_4) = (\mathcal{H}_1 \cap \mathcal{H}_3) \cup (\mathcal{H}_1 \cap \mathcal{H}_4) = \mathcal{I}(\overline{BAC}) \cup \mathcal{I}(\overline{B_1AC}),$$

we then have $P \in \mathcal{I}(\overline{BAC})$ or $P \in \mathcal{I}(\overline{B_1AC})$.

We get a contradiction if $l$ is either $AB$ or $AC$. For if $l = AB$, then we have $\angle BAP^\circ = 0$, $\angle PAC^\circ > 0$. Similarly if $l = AC$. 
We also get a contradiction if \( l \) contains a point \( P \neq A \) in \( \mathcal{R}(BAC) \) which is not on \( AC \). For then by 3.5.2 \( \angle BAP^\circ < \angle BAC^\circ \), so that 180\(^\circ\) − \( \angle BAP^\circ \) < 180\(^\circ\) − \( \angle BAC^\circ \) and so \( \angle BAC^\circ \) < \( \angle BAP^\circ \). It follows from 3.5.2 that \( A, C \in \mathcal{R}(BAP) \) and so \( \angle BAP^\circ + \angle CAP^\circ = \angle BAC^\circ \). But \( \angle BAC^\circ > 0 \) and so \( \angle CAP^\circ < \angle BAP^\circ \), which gives a contradiction.

Thus \( l \) must contain a point \( P \neq A \) in \( \mathcal{R}(BAC) \). Then \( \angle BAP^\circ + \angle PAC^\circ = \angle BAC^\circ \), we must have \( \angle BAP^\circ = \frac{1}{2} \angle BAC^\circ \) which determines \( A, P \) uniquely.

Definition. We define the mid-line or bisector of the angle-support \( BAC \) as follows:- if \( C \in [A, B] \) then it is the line \( AB \), and otherwise it is the unique line \( l \) just noted. We use the notation \( ml(BAC) \) for this.

### 3.7 DEGREE-MEASURE OF REFLEX ANGLES

3.7.1

Definition. Let \( \alpha \) be a reflex angle with support \( BAC \). We first suppose that \( C \not\in AB \), and as in 3.5.2 let \( \angle BAC_1 \) be the vertically opposite angle of the wedge-angle \( \angle BAC \). Then \( B_1 \not\in AC, C_1 \not\in AB \) and \( \angle B_1AC \) is the vertically opposite angle for \( \angle BAC_1 \). By 3.5.2 we note that

\[
180 + \angle B_1AC^\circ = \angle BAC_1^\circ + 180,
\]

and we define the degree-measure of \( \alpha \) to be the common value of these:

\[
\alpha^\circ = 180 + \angle BAC_1^\circ = \angle BAC^\circ + 180.
\]

Secondly, if \( C \in [A, B] \) so that \( \alpha \) is a full-angle, we define \( |\alpha|^\circ = 360 \).

Then for each reflex-angle \( \alpha \), \( |\alpha|^\circ \) is defined; by 3.5.2 it satisfies 180 < \( |\alpha|^\circ < 360 \) unless \( \alpha \) is a full-angle in which case \( |\alpha|^\circ = 360 \).

![Figure 3.12. Measure of a reflex angle.](image)

Let \( \alpha \) be a non-full reflex-angle with support \( BAC \) and take \( B_1 \neq A, C_1 \neq A \) so that \( A \in [B, B_1], A \in [C, C_1] \). Let \( A, D \subset \mathcal{R}(B_1AC_1) \) but \( D \not\in [A, C_1, D \not\in [A, B_1] \).
Then

\[
\angle BAD^\circ + \angle DAC^\circ = |\alpha|^\circ.
\]
**Proof.** As \([A,D \subset \mathcal{R}(|B_1AC_1|), D\) is in the closed half-plane with edge \(AB\) in which \(C_1\) lies, and also in the closed half-plane with edge \(AC\) in which \(B_1\) lies. By 3.5.2, \(|\angle B_1AD| < |\angle B_1AC_1|\) so by A5(iii) \(|\angle BAC| < |\angle BAD|\). By 3.5.2 then \([A,C_1 \subset \mathcal{R}(|BAD|), and by similar reasoning \([A,B_1 \subset \mathcal{R}(|DAC|). Then

\[
|\angle BAD| + |\angle DAC| = |\angle BAC| + |\angle B_1AC| = 180 + |\angle B_1AC| = |\alpha|.
\]

**COMMENT.** We could use this last result to employ the measures of reflex-angles to a significant extent, but in fact do not do so until our full treatment of them in Chapter 9.

**Exercises**

3.1 If \(B \in [A,C]\), then \(|A,B| \leq |A,P| \leq |A,C|\) for all \(P \in [B,C]\).

3.2 Let \(A,B,C\) be points of a line \(l\), and \(M = \text{mp}(A,B)\). If \(C\) is \(A\) or \(B\), or if \(C \in l \setminus [A,B]\), then \(|C,A| + |C,B| = 2|C,M|\).

3.3 Let \(A,B,C\) be distinct points and \(D = \text{mp}(B,C), E = \text{mp}(C,A), F = \text{mp}(A,B)\). Prove that \(D,E,F\) are distinct. If \(A \not\subset BC\), show that neither \(E\) nor \(F\) belongs to \(BC\).

3.4 If \(A \neq B\), show that

\[
\{P \in AB : |B,A| + |A,P| = |B,P|\}
\]

is the half-line of \(AB\) with initial-point \(A\) which does not contain \(B\), while

\[
[A,B = \{P \in AB : |A,P| + |P,B| = |A,B| or |A,B| + |B,P| = |A,P|\}.
\]

3.5 Find analogues of 3.3.1 when \(A \in [B,C]\) and when \(B \in [C,A]\).

3.6 Show that if \(A,B,C,D\) are distinct collinear points such that \(C \in [A,B]\), \(B \in [A,D]\), and

\[
\frac{|A,C|}{|C,B|} = \frac{|A,D|}{|D,B|}
\]

then

\[
\frac{1}{|A,C|} + \frac{1}{|A,D|} = \frac{2}{|A,B|}.
\]

3.7 Show that if \(A,B,C\) are non-collinear points, and \(P \neq A\) is a point of

\[\mathcal{R}(\{BAC\)}, then
\]

\[
\mathcal{R}(\{BAP\} \cup \mathcal{R}(\{PAC\}) = \mathcal{R}(\{BAC\}), \mathcal{R}(\{BAP\}) \cap \mathcal{R}(\{PAC\}) = [A,P].
\]
3.8 Show that if $d$ is any positive real number and $|\cdot|$ is a distance function, then $d|\cdot|$ is also a distance function.

3.9 If $\alpha$ is the reflex angle with support $|BAC|$ and $\beta$ is the reflex angle with support $|BAF|$, show that if $[A, F \subset R(|BAC)|$ then

$|\alpha|^\circ + |\angle CAF|^\circ = |\beta|^\circ$.

3.10 Prove that if $l = ml(|BAC|)$ and $m = ml(|BAC_1|)$ where $A \in [C, C_1]$, then $l \perp m$.

3.11 Suppose that $B, C, B_1$ and $C_1$ are points distinct from $A$ and that $A \in [B, B_1]$, $A \in [C, C_1]$. Show that then $ml(|B_1AC_1|) = ml(|BAC|)$. 
4

Congruence of triangles; parallel lines

COMMENT. In this chapter we deal with the notion of congruence of triangles, and make a start on the concept of parallelism of lines. As we have distance and angle-measure, we do not need special concepts of congruence of segments and congruence of angles, and we are able to define congruence of triangles instead of having it as a primitive term as in the traditional treatment. As a consequence there is a great gain in effectiveness and brevity.

4.1 PRINCIPLES OF CONGRUENCE

4.1.1 Congruence of triangles

\[
\begin{align*}
\text{Figure 4.1. Congruent triangles.}
\end{align*}
\]

\textbf{Definition.} Let } T \text{ be a triangle with the vertices } \{A, B, C\} \text{ and } T' \text{ a triangle with vertices } \{A', B', C'\}. \text{ We say that } T \text{ is congruent to } T' \text{ in the correspondence } A \to A', B \to B', C \to C', \text{ if }
\[
|B, C| = |B', C'|, \quad |C, A| = |C', A'|, \quad |A, B| = |A', B'|, \\
|\angle BAC|\degree = |\angle B'A'C'|\degree, \quad |\angle CBA|\degree = |\angle C'B'A'|\degree, \quad |\angle ACB|\degree = |\angle A'C'B'|\degree.
\]

We denote this by } T_{(A,B,C) \equiv (A',B',C')}^\rightarrow T'.

Geometry with Trigonometry
http://dx.doi.org/10.1016/B978-0-12-805066-8.50004-5
© 2016 Elsevier Ltd. All rights reserved.
We say that $T$ is congruent to $T'$, written $T \equiv T'$, if $T$ is congruent to $T'$ in at least one of the correspondences

$(A,B,C) \rightarrow (A',B',C'), (A,B,C) \rightarrow (A',C',B'), (A,B,C) \rightarrow (B',C',A'), (A,B,C) \rightarrow (B',A',C'), (A,B,C) \rightarrow (C',A',B'), (A,B,C) \rightarrow (C',B',A')$.

**COMMENT.** Originally, behind the concept of congruence lay the idea that $T$ can be placed on $T'$, fitting it exactly.

**AXIOM A.** If triangles $T$ and $T'$, with vertices $\{A,B,C\}$ and $\{A',B',C'\}$, respectively, are such that $|C,A| = |C',A'|$, $|A,B| = |A',B'|$, $|\angle BAC| = |\angle B'A'C'|$, then $T_{(A,B,C) \rightarrow (A',B',C')} \equiv T'$. In particular $|\angle ABC| = |\angle ACB|$.

**COMMENT.** This is known as the SAS (side, angle, side) principle of congruence for triangles.

**Triangles have the following properties:**

**If in a triangle** $[A,B,C]$: 

(i) $|A,B| = |A,C|$ then $|\angle ABC| = |\angle ACB|$;

(ii) $|A,B| = |A,C|$ and $D$ is the mid-point of $B$ and $C$, then $AD \perp BC$;

(iii) $B \neq C$, $D$ is the mid-point of $B$ and $C$, and $A \neq D$ is such that $AD \perp BC$, then $|A,B| = |A,C|$;

(iv) $\angle BAC$ is not straight, $E \in [A,B,F \in [A,C]$ are such that $|A,E| = |A,F| > 0$, and $G = mp(E,F)$, then $AG = ml(\angle BAC)$.

**Proof.**

(i) Note that for the triangle $T$ with vertices $\{A,B,C\}$, under the correspondence $(A,B,C) \rightarrow (A,C,B)$,

$|A,B| = |A,C|$, $|A,C| = |A,B|$, $|\angle BAC| = |\angle CAB|$, so by the SAS principle $T_{(A,B,C) \rightarrow (A,C,B)} \equiv T$. In particular $|\angle ABC| = |\angle ACB|$. 
(ii) Note that if $T_1, T_2$ are the triangles with vertices \{A, B, D\}, \{A, C, D\}, respectively, then

$$|A, B| = |A, C|, |B, D| = |C, D|,$$

$$|\angle ABD|^{\circ} = |\angle ACD|^{\circ},$$

so by the SAS principle, $T_1 \equiv_{(A,B,D)} T_2$. In particular $|\angle ADB|^{\circ} = |\angle ADC|^{\circ}$.

As $D \in [B, C]$, the sum of the degree-measures of these angles is 180 and so they must be right-angles.

(iii) As $AD \perp BC$ we know that $A \not\in BC$. If $T_1, T_2$ are the triangles with vertices \{A, B, D\}, \{A, C, D\}, respectively, then

$$|B, D| = |C, D|, |A, D| = |A, D|, |\angle BDA|^{\circ} = |\angle CDA|^{\circ},$$

so by the SAS principle, $T_1 \equiv_{(A,B,D)} T_2$. In particular $|A, B| = |A, C|$.

(iv) As in (ii), the triangles $[A, E, G], [A, F, G]$ are congruent, and so $|\angle EAG|^{\circ} = |\angle FAG|^{\circ}$.

**Definition.** A triangle is said to be **isosceles** if at least two of its sides have equal lengths.

**Proof.** Suppose that $|C', A'| \neq |C, A|$. Choose the point $D'$ on the half-line $[C', A'$ such that $|C', D'| = |C, A|$. Then if $T''$ is the triangle with vertices $\{B', C', D'\}$, under the correspondence $(B, C, A) \rightarrow (B', C', D')$ we have

$$|B, C| = |B', C'|, |C, A| = |C', D'|, |\angle BCA|^{\circ} = |\angle B'C'D'|^{\circ}.$$
Then by the SAS principle, \( T_{(B,C,A)} \overset{\sim}{\rightarrow} (B',C',D') \) \( T'' \). In particular

\[
\angle C'B'D' = \angle CBA = \angle C'B'A' \circ.
\]

Then we have different wedge-angles \( \angle C'B'A' \), \( \angle C'B'D' \), laid off on the same side of \( B'C' \) and having the same degree-measure. This gives a contradiction.

Thus \( |C',A'| = |C,A| \), and as we also have

\[
|C',B'| = |C,B|, \quad |\angle B'C'A'| = |\angle BCA| \circ,
\]

by the SAS principle we have \( T_{(B,C,A)} \overset{\sim}{\rightarrow} (B',C,A') \) \( T' \).

This is known as the ASA (angle, side, angle) principle of congruence.

If \( T \) and \( T' \) are triangles with vertices \( \{A,B,C\}, \{A',B',C'\} \), respectively, for which

\[
|B,C| = |B',C'|, \quad |C,A| = |C',A'|, \quad |A,B| = |A',B'|,
\]

then \( T_{(A,B,C)} \overset{\sim}{\rightarrow} (A',B',C) \) \( T' \).

**Figure 4.4. The SSS principle of congruence.**

**Proof.** Choose \( D \) on the opposite side of \( BC \) from \( A \), so that \( |\angle CBD| = |\angle C'B'A'| \circ \) and \( |B,D| = |B',A'| \). Let \( T'' \) be the triangle with vertices \( \{B,C,D\} \). Then as \( |B,C| = |B',C'| \), by the SAS principle

\[
T''_{(B,D,C)} \overset{\sim}{\rightarrow} (B',A',C) \) \( T' \).

Now \( |B,A| = |B',A'| = |B,D| \) so we have an isosceles triangle and \( |\angle BAD| = |\angle BDA| \circ \). Similarly

\[
|\angle CAD| = |\angle CDA| \circ.
\]

Note that \( A \) and \( D \) are on different sides of \( BC \), so a point \( E \) of \( [A,D] \) is on \( BC \).

**CASE 1.** Let \( E \in [B,C] \). Then \( [A,D] \subset J_{R}(BAC) \) and \( [D,A] \in J_{R}(BDC) \). It follows that

\[
|\angle BAC| = |\angle BAD| + |\angle DAC| = |\angle BDA| + |\angle ADC| = |\angle BDC| \circ.
\]
CASE 2. Let \( B \in [E, C] \). Then \([A, B] \in \mathcal{H}(\overline{DAC})\) and \([D, B] \in \mathcal{H}(\overline{ADC})\). It follows that

\[
|\angle BAC| = |\angle DAC| - |\angle DAB| = |\angle ADC| - |\angle ADB| = |\angle BDC|.
\]

CASE 3. Let \( C \in [B, E] \). Then \([A, C] \in \mathcal{H}(\overline{BAD})\) and \([D, C] \in \mathcal{H}(\overline{BDA})\). It follows that

\[
|\angle BAC| = |\angle BAD| - |\angle DAC| = |\angle BDA| - |\angle ADC| = |\angle BDC|.
\]

Now combining the cases, by the SAS principle, as \(|A, B| = |D, B|, |A, C| = |D, C|, |\angle BAC| = |\angle BDC|\), we have \( T_{(A, B, C)} \overset{\sigma}{\rightarrow} (D, B, C) T'' \). But \( T''_{(D, B, C)} \overset{\sigma}{\rightarrow} (A', B', C) T' \) so

\[ T_{(A, B, C)} \overset{\sigma}{\rightarrow} (A', B', C) T'. \]

This is known as the SSS(side, side, side) principle of congruence for triangles.

### 4.2 ALTERNATE ANGLES, PARALLEL LINES

#### 4.2.1 Alternate angles

Let \( A, B, C \) be non-collinear points, and take \( D \neq C \) so that \( C \in [A, D] \). Then \( |\angle BCD| > |\angle CBA| \).

**Proof.** Let \( E = \text{mp}(B, C) \) and choose \( F \) so that \( E = \text{mp}(A, F) \). Then if \( T_1, T_2 \) are the triangles with vertices \( \{A, B, E\}, \{F, C, E\} \), respectively, by the SAS principle of congruence \( T_1_{(A, B, E)} \overset{\sigma}{\rightarrow} (F, C, E) T_2 \). In particular,

\[
|\angle EBA| = |\angle ECF|, \text{ i.e. } |\angle CBA| = |\angle BCF|.
\]

But \([C, F] \in \mathcal{H}(\overline{BCD})\) as \( E \), and so \( F \), is in the closed half-plane with edge \( AC \) in which \( B \) lies, and \( D \) and \( F \) are on the opposite side of \( BC \) from \( A \). Also \( F \not\in AD \) as \( F \in AD \) would imply that \( E = C \). Then by 3.5.2 \( |\angle BCF| < |\angle BCD| \).

**COROLLARY 1.** In the theorem let \( G \neq C \) be such that \( C \in [B, G] \). Then \( |\angle ACG| > |\angle ABC| \).

**Proof.** This follows immediately as \( \angle ACG \) and \( \angle BCD \) are vertically opposite angles.
COMMENT. If \(D\) and \(H\) are on opposite sides of \(BC\), then \(\angle CBH\) and \(\angle BCD\) are known as \textbf{alternate angles}. This last result implies that if alternate angles \(\angle CBH\) and \(\angle BCD\) are equal in measure, then \(CD\) and \(BH\) cannot meet at some point \(A\).

\textbf{COROLLARY 2}. Given any line \(l\) and any point \(P \notin l\), there is a line \(m\) which contains \(P\) and is such that \(l \cap m = \emptyset\).

\textbf{Proof}. Take any points \(A, B \in l\) and lay off an angle \(\angle APQ\) on the opposite side of \(AP\) from \(B\), so that \(|\angle APQ|\circ = |\angle PAB|\circ\). Then by the recent comment the line \(PQ\) does not meet \(l\). In this \(\angle APQ\) and \(\angle PAB\) are alternate angles which are equal in measure.

4.2.2 Parallel lines

\textbf{Definition}. If \(l\) and \(m\) are lines in \(\Lambda\), we say that \(l\) is \textbf{parallel} to \(m\), written \(l \parallel m\), if \(l = m\) or \(l \cap m = \emptyset\).

Parallelism has the following properties:-

(i) \(l \parallel l\) for all \(l \in \Lambda\);

(ii) \(If \ l \parallel m \ then \ m \parallel l\);

(iii) \(Given\ any\ line\ \(l\ \in \Lambda\ \and\ any\ point\ \(P \in \Pi,\ there\ is\ at\ least\ one\ line\ \(m\ which\ contains\ \(P\ \and\ is\ such\ that\ \(l \parallel m\).

(iv) \(If\ the\ lines\ \(l\ \and\ \(m\ \are\ both\ perpendicular\ to\ the\ line\ \(n,\ then\ \(l\ \and\ \(m\ \are\ parallel\ to\ each\ other.\)

Figure 4.6. Parallel lines.
Proof.

(i) and (ii) follow immediately from the definition, while (iii) follows from 4.2.1.

(iv) As perpendicular lines form right-angles with each other at some point, \( l \) must meet \( n \) at some point \( A \), and \( m \) must meet \( n \) at some point \( P \) such that if \( B \) is any other point of \( l \) and \( Q \) is any point of \( m \) on the other side of \( n \) from \( B \), then \[ \angle PAB = 90, \quad \angle APQ = 90. \]

Then, as these are alternate angles equal in measure, by 4.2.1 Corollary 1, \( l \parallel m \).

4.3 PROPERTIES OF TRIANGLES AND HALF-PLANES

4.3.1 Side-angle relationships; the triangle inequality

If \( A, B, C \) are non-collinear points and \(|A, B| > |B, C|\), then \(|\angle ACB| > |\angle BAC|\), so that in a triangle a greater angle is opposite a longer side.

\[ \text{Figure 4.7. Angle opposite longer side.} \]

\[ \text{Figure 4.8. The triangle inequality.} \]

Proof. Choose \( D \in [B, A] \) so that \(|B, D| = |B, C|\). Then \( D \in [B, A] \) as \(|B, D| < |B, A|\).

Now \(|\angle ACB| > |\angle DCB|\) as \( |C, D| \subset \mathcal{R}(|BCA|) \), and \(|\angle DCB| = |\angle BDC|\) by 4.1.1. But \(|\angle BDC| > |\angle DAC|\) by 4.2.1 Corollary 1, so

\[ |\angle ACB| > |\angle DCB| = |\angle BDC| > |\angle DAC|. \]

Hence \(|\angle ACB| > |\angle DAC|\) and \( |\angle DAC| = |\angle BAC| \) as \( D \in [B, A] \).

**COROLLARY.** If \( A, B, C \) are non-collinear points and \(|\angle ACB| > |\angle BAC|\), then \(|A, B| > |B, C|\), so that in a triangle a longer side is opposite a greater angle.

Proof. For if \(|A, B| \leq |B, C|\), we have \(|\angle ACB| \leq |\angle BAC|\) by 4.1.1(i) and this result.

The triangle inequality. If \( A, B, C \) are non-collinear points, then \(|C, A| < |A, B| + |B, C|\).

Proof. Take a point \( D \) so that \( B \in [A, D] \) and \(|B, D| = |B, C|\).

As \(|C, B| \subset \mathcal{R}(|ACD|) \) we have \(|\angle DCA| > |\angle DCB|\). But \(|\angle DCB| = |\angle CDB|\)
by 4.1.1, so by our last result, \(|A,D| > |A,C|\). However \(|A,D| = |A,B| + |B,D|\) as \(B \in [A,D]\), and the result follows.

4.3.2 Properties of parallelism

Let \(l \in \Lambda\) be a line, \(G_1\) an open half-plane with edge \(l\) and \(P\) a point of \(G_1\). If \(m\) is a line such that \(P \in m\) and \(l \parallel m\), then \(m \subset G_1\).

**Proof.** As \(P \not\in l\), \(P \in m\) we have \(l \neq m\). Then as \(l \parallel m\) we have \(l \cap m = \emptyset\). Thus there cannot be a point of \(m\) on \(l\). Neither can there be a point \(Q\) of \(m\) in \(G_2\), the other open half-plane with edge \(l\). For then we would have \([P,Q] \cap l \neq \emptyset\) and so a point \(R\) of \(m\) would be on \(l\), as \([P,Q] \subset P Q = m\).

Let \(AB, CD\) be distinct lines and \(l\) distinct from and parallel to both. If \(l\) meets \([A,C]\) in a point \(E\), then \(l\) meets \([B,D]\) in a point \(F\).

**Proof.** By the Pasch property applied to \([A,B,C]\) as \(l\) does not meet \([A,B]\) it meets \([B,C]\) at some point \(G\). Then by the Pasch property applied to \([B,C,D]\), as \(l\) does not meet \([C,D]\) it meets \([B,D]\) in some point \(F\).

4.3.3 Dropping a perpendicular

Given any line \(l \in \Lambda\) and any point \(P \not\in l\), there is a unique line \(m\) such that \(P \in m\) and \(l \perp m\).
Proof.

Existence. Let $A, B$ be distinct points of $l$. Take a point $Q$ on the opposite side of $l$ from $P$ and such that $|\angle BAQ| = |\angle BAP|$. Also take $R \in [A, Q]$ so that $|A, R| = |A, P|$. As $P$ and $R$ are on opposite sides of $l$, $[P, R]$ meets $l$ in a point $S$.

We first suppose that $A \in PR$ so that $A \in S$. Then $[A, P, S]$ and $[A, R, S]$ are congruent by the SAS-principle, so in particular $|\angle ASP| = |\angle ASR|$. As $S \in [P, R]$ it follows that these are right-angles and so $PR \perp l$.

In the second case suppose that $A \notin PR$ so that $A = S$. Then $S \in [P, R]$ and by construction $|\angle BSR| = |\angle BSP|$. Again these are right-angles so $PR \perp l$.

Uniqueness. Suppose that there are distinct points $S, T \in l$ such that $PS \perp l$, $PT \perp l$. Choose $U \neq T$ so that $T \in [S, U]$. Then $|\angle UTP| = |\angle USP| = 90$ and this contradicts 4.2.1.

COMMENT. We refer to this last as dropping a perpendicular from the point $P$ to the line $l$.

Let $A, B, C$ be non-collinear points such that $AB \perp AC$ and let $D$ be the foot of the perpendicular from $A$ to $BC$. Then $D \in [B, C]$, $D \neq B$, $D \neq C$.

Proof. By 4.2.1, in a right-angled triangle each of the other two angles have degree-measure less than 90. By 4.3.1 it then follows that the side opposite the right-angle is longer than each of the other sides. It follows that $|B, D| < |A, B| < |B, C|$.

By a similar argument $|C, D| < |B, C|$. We cannot then have $B \in [C, D]$ as that would imply $|C, B| \leq |C, D|$, and similarly we cannot have $C \in [B, D]$ with as that would imply $|B, C| \leq |B, D|$. Hence $D \in [B, C]$, $D \neq B$, $D \neq C$.

4.3.4 Projection and axial symmetry

Definition. For any line $l \in \Lambda$ we define a function $\pi_l : \Pi \to l$ by specifying that for all $P \in \Pi$, $\pi_l(P)$ is the foot of the perpendicular from $P$ to $l$. We refer to $\pi_l$ as projection to the line $l$. 
**Definition.** For any line \( l \in \Lambda \) we define a function \( s_l : \Pi \to \Pi \) by specifying that for all \( P \in \Pi \), \( s_l(P) \) is the point \( Q \) such that 
\[
\pi_l(P) = \text{mp}(P, Q).
\]
We refer to \( s_l \) as **axial symmetry in the line** \( l \).

*Let \( \mathcal{H}_1, \mathcal{H}_2 \) be closed half-planes with common edge \( l \), let \( P_1 \in \mathcal{H}_1 \setminus l \) and \( P_2 = s_l(P_1) \). Then, for all \( P \in \mathcal{H}_1 \), \( |P, P_1| \leq |P, P_2| \).*

**Proof.** If \( P \in l \), then \( |P, P_1| = |P, P_2| \), by 4.1.1 when \( P \notin P_1P_2 \), and as \( P = \text{mp}(P_1, P_2) \) otherwise.

When \( P \in \mathcal{G}_1 = \mathcal{H}_1 \setminus l \) we suppose first that \( P \notin P_1P_2 \). Then \( [P, P_2] \) meets \( l \) in a point \( Q \) and we have
\[
|P, P_2| = |P, Q| + |Q, P_2| = |P, Q| + |Q, P_1|.
\]

Now we cannot have \( Q \in [P, P_1] \) as \( [P, P_1] \subset \mathcal{G}_1 \) and \( Q \in l \). Thus either \( Q \notin PP_1 \) or \( Q \in PP_1 \setminus [P, P_1] \). We then have \( |P, Q| + |Q, P| > |P, P_1| \) by 4.3.1 and 3.1.2. For the case when \( P \in P_1P_2 \), we denote by \( R \) the point of intersection of \( P_1P_2 \) and \( l \), so that \( R = \text{mp}(P_1, P_2) \).

Now \( P \in [R, P_1] \) so either \( P \in [R, P_1] \) or \( P_1 \in [R, P] \). In the first of these cases we have
\[
|P_1, P| < |P_1, R| = |R, P_2| < |P, P_2|,
\]
as \( R \in [P, P_2] \). In the second case we have \( |P, P_2| < |P, R| < |P, P_2| \) as \( R \in [P, P_2] \).

**Exercises**

4.1 If \( D \neq A \) is in \([A, B, C]\) but not in \([B, C]\), then \( |B, D| + |D, C| < |B, A| + |A, C| \) and \( |\angle BDC| > |\angle BAC| \).
4.2 There is an AAS-principle of congruence if
\[ |\angle BAC|^\circ = |\angle EDF|^\circ, \quad |\angle CBA|^\circ = |\angle FED|^\circ, \]
\[ |B, C| = |E, F|, \]
then the triangles \([A, B, C], [D, E, F]\) are congruent. [Hint. Suppose that \(|\angle BCA|^\circ < |\angle EFD|^\circ\); lay off an angle \(\angle BCG\) equal in magnitude to \(\angle EFD\) and with \(G\) on the same side of \(BC\) as \(A\) is; then \([C, G]\ meets \([A, B]\) at a point \(H\); also \([H, B, C] \equiv [D, E, F]\) and in particular \(|\angle BHC|^\circ = |\angle EDF|^\circ = |\angle BAC|^\circ\); deduce a contradiction and then apply the ASA-principle.]

4.3 There is an ASS-principle of congruence for right-angled triangles, that if \(BC \perp BA, \ EF \perp ED, \ |C, A| = |F, D|, \ |A, B| = |D, E|, \) then \([A, B, C] \equiv [D, E, F]\). [Hint. Take \(C'\) so that \(E \in [F, C']\) and \(|E, C'| = |B, C|.\]

4.4 If \(P \in ml([BCA])\) and \(Q = \pi_{AB}(P), \ R = \pi_{AC}(P)\), then \(|P, Q| = |P, R|\). Conversely, if \(P \in \mathcal{H}(\{BCA\})\) and \(|P, Q| = |P, R|\) where \(Q = \pi_{AB}(P), \ R = \pi_{AC}(P)\), then \(P \in ml([BCA]).\]

4.5 In triangles \([A, B, C], [D, E, F]\) let
\[ |A, B| = |D, E|, \ |A, C| = |D, F|, \ |\angle BAC| > |\angle EDF|. \]
Then \(|B, C| > |E, F|\). [Hint. Lay off the angle \(\angle BAG\) with \(|\angle BAG|^\circ = |\angle EDF|^\circ\) and with \(G\) on the same side of \(AB\) as \(C\) is. If \(G \in BC\) proceed; if \(G \notin BC\), let \(K = mp(G, C)\) and show that \([A, K\ meets \ [B, C] \ in a point \ H.\)]

4.6 If \(AB \parallel AC\), then \(AB = AC\).

4.7 Let \(\mathcal{H}_1\) be a closed half-plane with edge \(l\), let \(P \in \mathcal{H}_1\) and let \(O = \pi_l(P).\) Then if \(m\) is any line in \(\Lambda\) such that \(O \in m\), we must have \(\pi_m(P) \in \mathcal{H}_1.\]

4.8 With the notation of 4.1.1 show that in all cases \(T \underset{(A, B, C)}{\rightarrow} T'\) and if \(T \underset{(A, B, C)}{\rightarrow} (A', B', C')\) \(T' \rightarrow T''\) then \(T' \underset{(A', B', C')}{\rightarrow} T''\). Show also that if \(T \underset{(A, B, C)}{\rightarrow} (A', B', C')\) \(T' \rightarrow T''\) and \(T' \underset{(A', B', C')}{\rightarrow} (A'', B'', C'')\) \(T'' \rightarrow T''\) then \(T \underset{(A, B, C)}{\rightarrow} (A'', B'', C'')\). Thus congruence of triangles is reflexive, symmetric and transitive, and thus is an equivalence relation.
This page intentionally left blank
The parallel axiom; Euclidean geometry

COMMENT. The effect of introducing any axiom is to narrow things down, and depending on the final axiom still to be taken, we can obtain two quite distinct well-known types of geometry. By introducing our final axiom, we confine ourselves to the familiar school geometry, which is known as Euclidean geometry.

5.1 THE PARALLEL AXIOM

5.1.1 Uniqueness of a parallel line

We saw in 4.2 that given any line \( l \) and any point \( P \not\in l \) there is at least one line \( m \) such that \( P \in m \) and \( l \parallel m \). We now assume that there is only one such line ever.

AXIOM A7. Given any line \( l \in \Lambda \) and any point \( P \not\in l \), there is at most one line \( m \) such that \( P \in m \) and \( l \parallel m \).

COMMENT. By 4.2 and A7, given any line \( l \in \Lambda \) and any point \( P \in \Pi \), there is a unique line \( m \) through \( P \) which is parallel to \( l \).

Let \( l \in \Lambda \), \( P \in \Pi \) and \( n \in \Lambda \) be such that \( l \neq n \), \( P \in n \) and \( l \parallel n \). Let \( A \) and \( B \) be any distinct points of \( l \) and \( R \) a point of \( n \) such that \( R \) and \( B \) are on opposite sides of \( AP \). Then \( |\angle APR|^{\circ} = |\angle PAB|^{\circ} \), so that for parallel lines alternate angles must have equal degree-measures.

Proof. Let \( m \) be the line \( PQ \) in 4.2.1 such that \( |\angle APQ|^{\circ} = |\angle BAP|^{\circ} \). Then \( l \parallel m \). As \( m \) and \( n \) both contain \( P \) and \( l \) is parallel to both of them, by A7 we have \( m = n \), so that \( R \in [P, Q] \) and so \( |\angle APR|^{\circ} = |\angle APQ|^{\circ} \). Thus \( |\angle APR|^{\circ} = |\angle APQ|^{\circ} = |\angle PAB|^{\circ} \).

Let \( l, n \) be distinct parallel lines, \( A, B \in l \) and \( P, T \in n \) be such that \( B \) and \( T \) are on the one side of \( AP \), and \( S \neq P \) be such that \( P \in [A, S] \). Then the angles \( \angle BAP, \angle TPS \) have equal degree-measures.
**Proof.** Choose \( R \neq P \) so that \( P \in [T, R] \). Then \( R \in n \) and \( B \) and \( R \) are on opposite sides of \( AP \), so that \( \angle BAP, \angle APR \) are alternate angles and so have equal degree-measures. But \( \angle APR \) and \( \angle TPS \) are vertically opposite angles and so have equal degree-measures. Hence \( \angle BAP = \angle TPS \).

![Figure 5.1. Alternate angles.](image)

![Figure 5.2. Corresponding angles.](image)

We call such angles \( \angle BAP, \angle TPS \) **corresponding angles for a transversal.**

**Proof.** If \( l = n \), the result is trivial as \( l \parallel l \), so suppose \( l \neq n \). If \( l \) is not parallel to \( n \), then \( l \) and \( n \) will meet at some point \( P \), and then we will have distinct lines \( l \) and \( n \), both containing \( P \) and both parallel to \( m \), which gives a contradiction by A7. Thus parallelism is a transitive relation. Combined with the properties in 4.2.2 this makes it an equivalence relation.

If lines are such that \( l \perp n \) and \( l \parallel m \), then \( m \perp n \).

**Proof.** As \( l \) is perpendicular to \( n \) they must meet at some point \( A \). As \( l \parallel m \), we cannot have \( m \parallel n \), as by transitivity that would imply \( l \parallel n \). Thus \( m \) meets \( n \) in some point \( P \), and if we choose \( B \) on \( l \), \( Q \) on \( m \) on opposite sides of \( n \), then we have \( \angle APQ = \angle PAB \) as these are alternate angles for parallel lines. Hence \( \angle APQ = 90 \) and \( m \perp n \).

### 5.2 PARALLELOGRAMS

#### 5.2.1 Parallelograms and rectangles

**Definition.** Let points \( A, B, C, D \) be such that no three of them are collinear and \( AB \parallel CD, AD \parallel BC \). Let \( \mathcal{H}_1 \) be the closed half-plane with edge \( AB \) in which \( C \) lies; as \( CD \parallel AB \) then, by 4.3.2, \( D \in \mathcal{H}_1 \). Similarly let \( \mathcal{H}_3 \) be the closed half-plane with edge \( BC \) in which \( A \) lies; as \( AD \parallel BC \), then \( D \in \mathcal{H}_3 \). Thus \( D \in \mathcal{H}_1 \cap \mathcal{H}_3 = \mathcal{I} \mathcal{R}(\{ABC\}) \) and so by the cross-bar theorem \([A,C] \) meets \([B,D] \) in some point \( T \), which is unique.
as \( AC = BD \) would imply \( B \in AC \). Similarly \( C \in \mathcal{R}(BDA) \) so \( T \) is on \( [B,D] \). Thus \( [A,C] \cap [B,D] \neq \emptyset \) so as in 2.4.4 a convex quadrilateral \( [A,B,C,D] \) can be defined, and in this case it is called a parallelogram. The terminology of 2.4.4 then applies.

![Figure 5.3. A parallelogram.](image)

**Definition.** If \( [A,B,C,D] \) is a parallelogram in which \( AB \perp AD \), then, as \( AB \parallel CD \), by 5.1.1 we have \( AD \perp CD \). Thus if two adjacent side-lines of a parallelogram are perpendicular, each pair of adjacent side-lines are perpendicular; we call such a parallelogram a rectangle.

Parallelograms have the following properties:

(i) Opposite sides of a parallelogram have equal lengths.

(ii) The point of intersection of the diagonals of a parallelogram is the mid-point of each diagonal.

**Proof.**

(i) With the notation above for a parallelogram, the triangles with vertices \( \{A,B,D\} \) and \( \{C,D,B\} \) are congruent in the correspondence \( (A,B,D) \rightarrow (C,D,B) \) by the ASA principle. First note that \( |B,D| = |D,B| \). Secondly note that \( AB \parallel CD \) and \( A \) and \( C \) are on opposite sides of \( BD \) so that \( \angle ABD \) and \( \angle CDB \) are alternate angles, and hence \( \angle ABD = \angle CDB \). Finally \( AD \parallel BC \), and \( A \) and \( C \) are on opposite sides of \( BD \), so that \( \angle ADB \) and \( \angle CBD \) are alternate angles and hence \( \angle ADB = \angle CBD \). It follows that \( |A,B| = |C,D|, \ |A,D| = |B,C| \).

(ii) Let \( T \) be the point of intersection of the diagonals. Then the triangles \( [A,B,T], [C,D,T] \) are congruent by the ASA principle, as

\[
|A,B| = |C,D|, \ |\angle ABT| = |\angle CDT|, \ |\angle BAT| = |\angle DCT|.
\]

It follows that \( |A,T| = |C,T|, \ |B,T| = |D,T| \).

5.2.2 Sum of measures of wedge-angles of a triangle

If \( A,B,C \) are non-collinear points, then

\[
\angle CAB + \angle ABC + \angle BCA = 180.
\]
Thus the sum of the degree-measures of the wedge-angles of a triangle is equal to 180.

**Proof.** Let \( l \) be the line through \( A \) which is parallel to \( BC \). If \( m \) is the line through \( B \) which is parallel to \( AC \), then we cannot have \( l \parallel m \) as we would then have \( l \parallel AC \); we would then have \( BC \parallel l \), \( l \parallel AC \) and so \( BC \parallel AC \); thus as \( BC \cap AC \neq \emptyset \) we would have \( BC = AC \); this would make \( A, B, C \) collinear and contradict our assumption.

Thus \( m \) meets \( l \) at some point, \( Q \) say. Then \( [A, C, B, Q] \) is a parallelogram and \( [A, B], [Q, C] \) meet at a point \( T \). Now \( Q \) is on the opposite side of \( AB \) from \( C \), so that \( \angle CBA \) and \( \angle BAQ \) are alternate angles and so \( |\angle CBA| = |\angle BAQ| \). Moreover \( [A, B] \subset I \overline{R}([CAQ]) \) and so \( |\angle CAB| + |\angle BAQ| = |\angle CAQ| \).

Choose \( R \neq A \) so that \( A \in [Q, R] \). Then \( R \in l \) and \( R \) is on the opposite side of \( AC \) from \( Q \). But \( BQ \parallel AC \) so \( B \) and \( Q \) are on the same side of \( AC \), and hence \( B \) and \( R \) are on opposite sides of \( AC \). Then \( \angle CBA \) and \( \angle CAR \) are alternate angles, so \( |\angle CBA| = |\angle CAR| \). Thus

\[
(|\angle CAB| + |\angle CBA|) + |\angle BCA| = (|\angle CAB| + |\angle BAQ|) + |\angle BCA|
\]

\[
= |\angle CAQ| + |\angle CAR|
\]

\[
= 180.
\]

**COROLLARY.** If the points \( A, B, C \) are non-collinear, and \( D \neq C \) is chosen so that \( C \in [B, D] \), then \( |\angle ACD| = |\angle BAC| + |\angle CBA| \). Thus the degree-measure of an exterior wedge-angle of a triangle is equal to the sum of the degree-measures of the two remote wedge-angles of the triangle.

**Proof.** For each of these is equal to \( 180 - |\angle ACB| \), as \( C \in [B, D] \).

### 5.3 RATIO RESULTS FOR TRIANGLES

#### 5.3.1 Lines parallel to one side-line of a triangle

Let \( A, B, C \) be non-collinear points, and with \( l = AB \), \( m = AC \), let \( A \leq l \leq m \) be natural orders such that \( A \leq l \leq B \), \( A \leq m \leq C \). Let \( D_1, D_2, D_3 \) be points of \( AB \) such that \( A \leq l \leq D_1 \leq l \leq D_2 \leq l \leq D_3 \leq l \leq B \) and \( |D_1, D_2| = |D_2, D_3| \), so that \( D_2 \) is the mid-point of \( D_1 \) and \( D_3 \). Then the lines through \( D_1, D_2 \) and \( D_3 \) which are all parallel to \( BC \), will meet \( AC \) in points \( E_1, E_2, E_3 \), respectively, such that \( A \leq m \leq E_1 \leq m \leq E_2 \leq m \leq E_3 \leq m \leq C \) and \( |E_1, E_2| = |E_2, E_3| \).
Sec. 5.3  

**Ratio results for triangles**

**Proof.** By Pasch’s property in 2.4.3 applied to the triangle \([A, B, C]\), the lines through \([D_1, D_2, D_3]\) which are parallel to \(BC\) will meet \([A, C]\) in points \(E_1, E_2, E_3\), respectively. By Pasch’s property applied to \([A, D_3, E_3]\), since \(D_2 \in [A, D_3]\) and the lines through \(D_2\) and \(D_3\) parallel to \(BC\) are parallel to each other, \(E_2 \in [A, E_3]\).

By Pasch’s property applied to \([A, D_2, E_2]\), since \(D_1 \in [A, D_2]\) and the lines through \(D_1\) and \(D_2\) parallel to \(BC\) are parallel to each other, \(E_1 \in [A, E_2]\). It remains to show that \(E_2\) is equidistant from \(E_1\) and \(E_3\).

By Pasch’s property applied to \([A, D_2, E_2]\), since \(E_1 \in [A, E_2]\) the line through \(E_1\) which is parallel to \(AB = AD_2\) will meet \([D_2, E_2]\) in a point \(F\). By Pasch’s property applied to \([A, D_2, E_2]\), since \(E_2 \in [A, E_3]\) the line through \(E_2\) which is parallel to \(AB = AD_3\) will meet \([D_3, E_3]\) in a point \(G\).

Let \(T_1, T_2\) be the triangles with vertices \(\{E_1, F, E_2\}, \{E_2, G, E_3\}\), respectively. Our objective is to show that

\[
T_1 \xrightarrow{(E_1, F, E_2) \sim (E_2, G, E_3)} T_2.
\]

Now \(D_1E_1 \parallel D_2F, D_1D_2 \parallel E_1F\), so \([D_1, D_2, F, E_1]\) is a parallelogram, and so by 5.2.1 \(|D_1, D_2| = |E_1, F|\). Similarly \(D_2E_2 \parallel D_3G, D_2D_3 \parallel E_2G\) so \([D_2, D_3, G, E_2]\) is a parallelogram, and so \(|D_2, D_3| = |E_2, G|\). But \(|D_1, D_2| = |D_2, D_3|\) and hence \(|E_1, F| = |E_2, G|\).

Let \(\mathcal{H}_1\) be the closed half-pane with edge \(AC\) in which \(B\) lies. Then \([A, B] \subset \mathcal{H}_1\), so \(D_2, D_3 \subset \mathcal{H}_1\). Then \([D_2, E_2], [D_3, E_3] \subset \mathcal{H}_1\), so \(F, G \in \mathcal{H}_1\). Then \(F\) and \(G\) are on the one side of the line \(AC\), and as \(D_2E_2 \parallel D_3E_3\) and \(E_2 \in [E_3, E_1]\), the angles \(\angle FE_2E_1, \angle GE_3E_2\) are corresponding angles for parallel lines and so have equal degree-measures. Thus \(|\angle FE_2E_1| = \angle GE_3E_2|\).

By transitivity \(E_1F \parallel EG\) as both are parallel to \(AB, F\) and \(G\) are on the one side of \(AC\), and \(E_2 \in [E_1, E_3]\), so the angles \(\angle FE_1E_2\) and \(\angle GE_2E_3\) are corresponding angles for parallel lines and so have equal degree-measures. Thus \(|\angle FE_1E_2| = \angle GE_2E_3|\).

As \(|\angle FE_2E_1| = \angle GE_3E_2|, |\angle FE_1E_2| = \angle GE_2E_3|,\) by 5.2.2 \(|\angle E_1FE_2| = \angle GE_2E_3|\). Thus

\[
|E_1, F| = |E_2, G|, |\angle FE_1E_2| = \angle GE_2E_3|, |\angle E_1FE_2| = \angle GE_2E_3|,
\]

so by the ASA principle, the triangles \(T_1, T_2\) are congruent in the correspondence \((E_1, F, E_2) \rightarrow (E_2, G, E_3)\). It follows that \(|E_1, E_2| = |E_2, E_3|\).
Let $A, B, C$ be non-collinear points and let $P \in [A, B]$ and $Q \in [A, C]$ be such that $PQ \parallel BC$. Then

$$\frac{|A, P|}{|A, B|} = \frac{|A, Q|}{|A, C|}.$$ 

**Proof.** We assume first that $P \in [A, B]$. Within this first case, we suppose initially that

$$\frac{|A, P|}{|A, B|} = \frac{s}{t},$$

where $s$ and $t$ are positive whole numbers with $s < t$, so that $s/t$ is an arbitrary rational number between 0 and 1. For $0 \leq j \leq t$ let $B_j$ be the point on $[A, B]$ such that

$$\frac{|A, B_j|}{|A, B|} = \frac{j}{t},$$

so that $B_0 = A$, $B_t = B$ and $B_s = P$. If $AB = l$ and $\leq l$ is the natural order for which $A \leq_l B$, then $A \leq_l B_{j-1} \leq_l B_j \leq_l B_{j+1} \leq_l B$ and $|B_{j-1}, B_j| = |B_j, B_{j+1}|$. If $AC = m$ and $\leq_m$ is the natural order for which $A \leq_m C$, then by the last result applied with $(D_1, D_2, D_3) = (B_{j-1}, B_j, B_{j+1})$, for $1 \leq j \leq t$ the line through $B_j$ which is parallel to $BC$ will meet $AC$ in a point $C_j$ such that $A \leq_m C_{j-1} \leq_m C_j \leq_m C_{j+1} \leq_m C$ and $|C_{j-1}, C_j| = |C_j, C_{j+1}|$.

It follows that, for $0 \leq j \leq t$, $|A, C_j| = j|A, C_1|$ and so as $C_t = C$,

$$\frac{|A, C_j|}{|A, C|} = \frac{j |A, C_1|}{t |A, C_1|} = \frac{j}{t}.$$ 

In particular, as $C_s = Q$, it follows that

$$\frac{|A, Q|}{|A, C|} = \frac{s}{t} = \frac{|A, P|}{|A, B|}.$$
Still within the first case, now suppose that
\[
\frac{|A, P|}{|A, B|} = x, \quad \frac{|A, Q|}{|A, C|} = y,
\]
where \(x\) is an irrational number with \(0 < x < 1\). If \(u\) is any positive rational number less than \(x\), and \(P_u\) is a point chosen on \([A, B]\) so that
\[
\frac{|A, P_u|}{|A, B|} = u,
\]
then the line through \(P_u\) which is parallel to \(BC\) will meet \([A, C]\) in a point \(Q_u\) such that
\[
|A, Q_u| = u.
\]
Similarly if \(v\) is any rational number such that \(x < v < 1\), and \(P_v\) is a point chosen on \([A, B]\) so that
\[
\frac{|A, P_v|}{|A, B|} = v,
\]
then the line through \(P_v\) which is parallel to \(BC\) will meet \([A, C]\) in a point \(Q_v\) such that
\[
|A, Q_v| = v.
\]
As \(|A, P_u| < |A, P| < |A, P_v|\) we have \(P \in [P_u, P_v]\). It follows by 4.3.2 that \(Q \in [Q_u, Q_v]\) and so \(u < y < v\). Thus for all rational \(u\) and \(v\) such that \(u < x < v\) we have \(u < y < v\). It follows that \(x = y\).

This completes the first case. For the second case note that if \(P \not\in [A, B]\) we have \(B \in [A, P]\). Then by the first case
\[
\frac{|A, B|}{|A, P|} = \frac{|A, C|}{|A, Q|},
\]
so the reciprocals of these are equal.

### 5.3.2 Similar triangles

Let \(A, B, C\) and \(A', B', C'\) be two sets of non-collinear points such that
\[
\angle BAC = \angle B'A'C', \quad \angle CBA = \angle C'B'A', \quad \angle ACB = \angle A'C'B'.
\]
Then
\[
\frac{B', C'}{B, C} = \frac{C', A'}{C, A} = \frac{A', B'}{A, B}.
\]
Thus if the degree-measures of the angles of one triangle are equal, respectively, to the degree-measures of the angles of a second triangle, then the ratios of the lengths of corresponding sides of the two triangles are equal.
**Proof.** Choose \( B'' \in [A, B] \) and \( C'' \in [A, C] \) so that \(|A, B''| = |A', B'|, |A, C''| = |A', C'|\). Then as \( \angle B''AC''^\circ = \angle BAC^\circ = \angle B'A'C'|^\circ \), by the SAS principle we see that the triangles \([A, B'', C'']\), \([A', B', C']\) are congruent in the correspondence \((A, B'', C'') \rightarrow (A', B', C')\). In particular \( \angle AB''C''^\circ = \angle A'B'C'|^\circ \) and so \( \angle AB''C''^\circ = \angle ABC^\circ \). These are corresponding angles in the sense of 5.1.1, so \( B''C'' \parallel BC \) and then by 5.3.1

\[
\frac{|A, B''|}{|A, B|} = \frac{|A, C''|}{|A, C|},
\]

so

\[
\frac{|A', B'|}{|A, B|} = \frac{|A', C'|}{|A, C|}.
\]

By a similar argument on taking a triangle \([B, E, F]\) which is congruent to \([B', C', A']\), we have

\[
\frac{|B', C'|}{|B, C|} = \frac{|B', A'|}{|B, A|}.
\]

**Comment.** Triangles like these, which have the degree-measures of corresponding angles equal and so the ratios of the lengths of corresponding sides are equal, are said to be **similar** in the correspondence \((A, B, C) \rightarrow (A', B', C')\).

Let \( A, B, C \) and \( A', B', C' \) be two sets of non-collinear points such that

\[
\frac{|A', B'|}{|A, B|} = \frac{|A', C'|}{|A, C|}, \quad \angle B'A'C'|^\circ = \angle BAC^\circ.
\]

Then the triangles are similar.

**Proof.** Choose \( B'' \in [A, B] \), \( C'' \in [A, C] \) so that \(|A, B''| = |A', B'|, |A, C''| = |A', C'|\). Then as \( \angle B'A'C'|^\circ = \angle BAC^\circ = \angle B''AC''^\circ \), by the SAS principle we see that the triangles \([A', B', C']\), \([A, B'', C'']\) are congruent. We note that

\[
\frac{|A, B''|}{|A, B|} = \frac{|A, C''|}{|A, C|}.
\]
Now the line through $B''$ which is parallel to $BC$ will meet $[A, C]$ in a point $D$ such that

$$\frac{|A, B''|}{|A, B|} = \frac{|A, D|}{|A, C|}.$$ 

Hence

$$\frac{|A, C''|}{|A, C|} = \frac{|A, D|}{|A, C|},$$

from which it follows that $|A, D| = |A, C''|$. As $C'', D \in [A, C]$ we then have $D = C''$ and so $B''C'' \parallel BC$. Thus the degree-measures of the angles of $[A, B, C]$ are equal to those of the corresponding angles of $[A, B'', C'']$ and so in turn to those of the corresponding angles in $[A', B', C']$.

### 5.4 PYTHAGORAS’ THEOREM, c. 550B.C.

#### 5.4.1 Pythagoras’ theorem

**Pythagoras’ theorem.** Let $A, B, C$ be non-collinear points such that $AB \perp AC$. Then

**Proof.** Let $D$ be the foot of the perpendicular from $A$ to $BC$; then by 4.3.3 $D$ is between $B$ and $C$. The triangles $[D, B, A]$, $[A, B, C]$ are similar as $|\angle ADB| = |\angle CAB| = 90$, $|\angle DBA| = |\angle ABC|$, and then by 5.2.2 $|\angle BAD| = |\angle BCA|$. Then by the last result

$$\frac{|A, B|}{|B, C|} = \frac{|B, D|}{|A, B|},$$

Figure 5.8. Pythagoras’ theorem.

Figure 5.9. Impossible figure for converse.
CONVERSE of PYTHAGORAS’ THEOREM. Let $A, B, C$ be non-collinear points such that

Then $\angle BAC$ is a right-angle.

**Proof.** Choose the point $E$ so that $|A, C| = |A, E|$, $E$ is on the same side of $AB$ as $C$ is, and $\angle BAЕ$ is a right-angle. By Pythagoras’ theorem,

Thus $|B, E| = |B, C|$, and the lengths of the sides of the triangle $[B, A, C]$ are equal to those of $[B, A, E]$. By the SSS principle, $[B, A, C] \equiv [B, A, E]$. In particular $\angle BAC^\circ = \angle BAE^\circ$ and this latter is a right-angle by construction. In fact $E = C$.

**NOTE.** In a right-angled triangle, the side opposite the right-angle is known as the hypotenuse.

## 5.5 MID-LINES AND TRIANGLES

### 5.5.1 Harmonic ranges

Let $A, B, C$ be non-collinear points such that $|A, B| > |A, C|$. Take $D \neq A$ so that $A \in [B, D]$. Then the mid-lines of $[BAC]$ and $[CAD]$ meet $BC$ at points $E, F$, respectively, such that $\{E, F\}$ divide $[B, C]$ internally and externally in the same ratio.

![Figure 5.10](image)

**Proof.** By the cross-bar theorem the mid-line of $[BAC]$ meets $[B, C]$ in a point $E$. Let $G$ be a point of the mid-line of $[CAD]$, on the same side of $AB$ as $C$ is. We cannot have $AG \parallel BC$ as that would imply

$$\angle BCA^\circ = \angle CAG^\circ = \angle GAD^\circ = \angle CBA^\circ,$$

and this in turn would imply that $|A, B| = |A, C|$, contrary to hypothesis. Then $AG$ meets $BC$ in some point $F$.

Take $H \in [A, D]$ so that $|A, H| = |A, C|$. Then $\angle AHC^\circ = \angle ACH^\circ$. We have that

$$\angle BAC^\circ = \angle AHC^\circ + \angle ACH^\circ, \quad \angle AHC^\circ = \angle ACH^\circ,$$

$$\angle BAC^\circ = \angle BAE^\circ + \angle EAC^\circ, \quad \angle BAE^\circ = \angle EAC^\circ.$$
It follows that $|\angle EAC| = |\angle ACH|$, and as $E, H$ are on opposite sides of $AC$ this implies that $AE \parallel HC$. It then follows that

$$\frac{|B, E|}{|E, C|} = \frac{|B, A|}{|A, H|} = \frac{|B, A|}{|A, C|}.$$

$$|\angle HAC| = |\angle AKC| + |\angle ACK|, \quad |\angle AKC| = |\angle ACK|,$$

$$|\angle HAC| = |\angle HAG| + |\angle GAC|, \quad |\angle HAG| = |\angle GAC|.$$

It follows that $|\angle GAC| = |\angle ACK|$. But $H, K$ are on opposite sides of $AC$, $H, G$ are on the same side, and so $G, K$ are on opposite sides. This implies that $AG \parallel KC$. Now $AG$ meets $BC$ at $F$, and $K \in [A, B]$ so $C \in [B, F]$. It follows that

$$\frac{|B, F|}{|F, C|} = \frac{|B, A|}{|A, K|} = \frac{|B, A|}{|A, C|}.$$

On combining the two results, we then have

$$\frac{|B, E|}{|E, C|} = \frac{|B, F|}{|F, C|}.$$

**NOTE.** We also refer to the mid-line of $|CAD|$ above as the **external bisector** of $|BAC|$. When $\{E, F\}$ divide $|B, C|$ internally and externally in the same ratio, we say that $(B, C, E, F)$ form a **harmonic range**.

Let $(A, B, C, D)$ be a harmonic range and $S \notin AB$. Let the line through $C$, parallel to $SD$, meet $SA$ at $G$ and $SB$ at $H$. Then $C$ is the mid-point of $G$ and $H$.

\[\text{Figure 5.11.}\]

**Proof.** We are given

$$\frac{|A, C|}{|C, B|} = \frac{|A, D|}{|D, B|},$$

so

$$\frac{|A, C|}{|A, D|} = \frac{|C, B|}{|D, B|}.$$
As $GC \parallel SD$ the triangles $[A, D, S]$ and $[A, C, G]$ are similar, so

$$\frac{|A, C|}{|A, D|} = \frac{|G, C|}{|S, D|}.$$

In the similar triangles $[B, C, H]$ and $[B, D, S]$,

$$\frac{|B, C|}{|B, D|} = \frac{|C, H|}{|S, D|}.$$

Then

$$\frac{|G, C|}{|S, D|} = \frac{|C, H|}{|S, D|}.$$

It follows that $|G, C| = |C, H|$.

Let $(A, B, C, D)$ be a harmonic range, $S \notin AB$ and $K \neq S$ be such that $S \in [A, K]$. Suppose that $CS \perp DS$. Then $CS$ and $DS$ are the mid-lines of $|ASB|$ and $|BSK|$.

**Proof.** Let the line through $C$, parallel to $DS$ meet $SA$ at $G$ and $SB$ at $H$. Then $C$ is the mid-point of $G$ and $H$. Also $CS \perp SD$, $SD \parallel GH$ so $SC \perp GH$. It follows that the triangles $[G, C, S]$ and $[H, C, S]$ are congruent by the SAS-principle. In particular $\angle GSC^\circ = \angle HSC^\circ$ and so $SC$ is the mid-line of $|ASB|$. But also $\angle CGS^\circ = \angle CHS^\circ$ and in fact the triangle $[S, G, H]$ is isosceles. Now $\angle CGS$ and $\angle DSK$ are corresponding angles and $\angle CHS$ and $\angle DSH$ are alternate angles. It follows that $\angle DSK^\circ = \angle DSH^\circ$ and so the mid-line of $|BSK|$ is $SD$.

### 5.6 AREA OF TRIANGLES, AND CONVEX QUADRILATERALS AND POLYGONS

#### 5.6.1 Area of a triangle

Let $A, B, C$ be non-collinear points, and $D \in BC$, $E \in CA$, $F \in AB$ points such that $AD \perp BC$, $BE \perp CA$, $CF \perp AB$. Then

Proof.

The triangles \([A, B, E]\) and \([A, C, F]\) are similar in the correspondence \((A, B, E) \rightarrow (A, C, F)\), as \(\angle BAE = \angle CAF\) is in both, \(\angle AEB^\circ = \angle AFC^\circ = 90\), and then by 5.2.2 \(\angle ABE^\circ = \angle ACF^\circ\). By 5.3.2

\[
\frac{|B, E|}{|C, F|} = \frac{|A, B|}{|C, A|}.
\]

On cross multiplication,

\[|B, E||C, A| = |C, F||A, B|\).

By a similar argument, we can show that \(|A, D||B, C|\) is equal to these.

**Definition.** With the notation of the last result, the **area** of the triangle \([A, B, C]\), denoted by \(\Delta[A, B, C]\), is the common value of:

\[
\frac{1}{2}|A, D||B, C|, \quad \frac{1}{2}|B, E||C, A|, \quad \frac{1}{2}|C, F||A, B|.
\]

**Area of triangles has the following properties:-**

(i) **If** \(P \in [B, C]\) **is distinct from** \(B\) **and** \(C\), **then**

(ii) **If** \([A, B, C, D]\) **is a convex quadrilateral, then**

(iii) **If two triangles are congruent then their areas are equal.**
**Proof.**

(i) For $D$ is the foot of the perpendicular from the vertex $A$ to the opposite side-line in each of the triangles $[A, B, P]$ and $[A, P, C]$, so with $p_1 = |A, D|$ we have

$$\Delta[A, B, P] = \frac{1}{2} p_1 |B, P|, \quad \Delta[A, P, C] = \frac{1}{2} p_1 |P, C|,$$

and the sum of these is

$$\frac{1}{2} p_1 (|B, P| + |P, C|) = \frac{1}{2} p_1 |B, C|,$$

as $P \in [B, C]$.

(ii) As in 5.2.1 denote by $T$ the point which $[A, C]$ and $[B, D]$ have in common. Then by (i) above,

$$\Delta[A, B, D] + \Delta[C, B, D] = (\Delta[A, B, T] + \Delta[A, D, T]) + (\Delta[C, B, T] + \Delta[C, D, T]),$$

and these are clearly equal.

(iii)

Let $T$ be a triangle with vertices $\{A, B, C\}$ and $T'$ a triangle with vertices $\{A', B', C'\}$ such that $T \cong_{(A, B, C)} T'$. Suppose that $D$ and $D'$ are the feet of the perpendiculars from $A$ and $A'$ onto $BC$ and $B'C'$, respectively.

There are three cases to be considered.
First suppose that \(D = B\). Then \(|\triangle ABC| = 90 = |\triangle A'B'C'|\) and so \(D' = B'\). Then
\[
\frac{1}{2}|A,D||B,C| = \frac{1}{2}|A,B||B,C| = \frac{1}{2}|A',B'||B',C'| = \frac{1}{2}|A',D'||B',C'|,
\]
so the areas are equal. There is a similar proof when \(D = C\).

Secondly suppose that \(D\) lies in \([B,C]\) but is not \(B\) or \(C\). Then the angles \(\angle CBA = \angle DBA\) and \(\angle BCA = \angle DCA\) are both acute. It follows that the angles \(\angle C'B'A'\) and \(\angle B'C'A'\) are both acute and so \(D'\) lies in \([B',C']\) but is not \(B'\) or \(C'\).

Now the triangles with vertices \(\{A,B,D\}\) and \(\{A',B',D'\}\) have two angles pairwise equal in magnitude and so the third angles \(\angle DAB\) and \(\angle D'A'B'\) are also equal. Then by the ASA principle of congruence these two triangles are congruent in the correspondence \((A,B,D) \rightarrow (A',B',D')\). In particular \(|A,D| = |A',D'|\) and so
\[
\frac{1}{2}|A,D||B,C| = \frac{1}{2}|A',D'||B',C'|. 
\]
Thus the areas are equal.

Thirdly suppose that \(C\) lies in \([B,D]\) but is not \(D\). Then the angles \(\angle CBA = \angle DBA\) and \(\angle DCA\) are acute and the angle \(\angle BCA\) is obtuse. It follows that \(\angle C'B'A'\) is acute and \(\angle B'C'A'\) is obtuse and so \(C'\) lies in \([B',D']\) but is not \(D'\). Now the triangles with vertices \(\{A,B,D\}\) and \(\{A',B',D'\}\) are congruent as in the second case and so the equality of areas follows. There is a similar proof when \(B\) lies in \([D,C]\) but is not \(D\), on interchanging the roles of \(B\) and \(C\) in this last argument.

### 5.6.2 Area of a convex quadrilateral

**NOTE.** In the quadrilateral in Figure 5.14 we have
\[
\]
\[
\]
\[
= \Delta[B,A,C] + \Delta[D,A,C].
\]

**Definition.** We define the **area of the convex quadrilateral** \([A,B,C,D]\) as in Figure 5.14 to be
\[
\Delta[A,B,D] + \Delta[C,B,D] = \Delta[B,A,C] + \Delta[D,A,C],
\]
and denote it by \(\Delta[A,B,C,D]\).

*If \([A,B,C,D]\) is a rectangle, then*
\[
\Delta[A,B,C,D] = |A,B||B,C|,
\]
*that is the area is equal to the product of the lengths of two adjacent sides.*

**Proof.** For \(\Delta[A,B,D] = \frac{1}{2}|A,B||A,D|\), \(\Delta[C,B,D] = \frac{1}{2}|D,C||B,C|\). As by 5.2.1 \(|D,C| = |A,B|\) and \(|B,C| = |A,D|\), the result follows by addition.

### 5.6.3 Area of a convex polygon

As a preparation for generalisation we first show that in 2.4.4 for the convex quadrilateral \([A,B,C,D]\) we have \(C \in \mathcal{H}_1, D \in \mathcal{H}_3, A \in \mathcal{H}_5\), and \(B \in \mathcal{H}_7\), so that each of the vertices is in each of these closed half-planes.
We cannot have \( A = T \) as then we would have \( A \in BD \); nor can \( T \) be any other point of the line \( AB \), for then we would have \( AT = AB \) and so \( C \in AB \). Thus \( T \not\in AB \) and similarly \( T \) is not on any of the other side-lines.

As \( B, D \in \mathcal{H}_1 \) and \( T \in [B, D] \) we have \( T \in \mathcal{H}_1 \). Then \( A \in AB \), \( T \in \mathcal{H}_1 \) and \( T \neq A \) so by 2.2.3(iv) \([A, T] \subset \mathcal{H}_1 \). Now \( A, T, C \) are distinct and collinear and \( T \in [A, C] \) so by 2.1.4(v) we cannot have \( A \in [T, C] \). Thus \( C \in [A, T] \) and so \( C \in \mathcal{H}_1 \). By a similar argument the other cases follow.

We now establish a converse of this, starting with \( A, B, C, D \) as in 2.4.4, with no three of them collinear and \( \mathcal{H}_1, \mathcal{H}_3, \mathcal{H}_5, \mathcal{H}_7 \) as defined there. We now suppose that \( C \in \mathcal{H}_1, D \in \mathcal{H}_3, A \in \mathcal{H}_5, B \in \mathcal{H}_7 \) and wish to prove that \([A, C] \cap [B, D] \neq \emptyset \).

To start with we note that \( \mathcal{H}_1 \cap \mathcal{H}_3 = I \mathcal{R}(|ABC) \) and \([A, C] \) is a cross-bar of this. Now we are given that \( D \in \mathcal{H}_1, D \in \mathcal{H}_3 \) so \( D \) is in this interior region and by the cross-bar theorem in 3.4.1 \([B, D] \) meets \([A, C] \) in a point \( T \). Similarly \( \mathcal{H}_1 \cap \mathcal{H}_7 = I \mathcal{R}(|BAD) \) and \([B, D] \) is a cross-bar of this. Thus \( C \) is in this interior region and by the cross-bar theorem \([A, C] \) meets \([B, D] \) in some point. But the lines \( AC \) and \( BD \) can meet only once as otherwise we would have \( AC = BD \) which is ruled out. Thus we have \( T \in [B, D] \) as well.

**Definition.** For an integer \( n \geq 3 \) let \( P_1, P_2, \ldots, P_n \) be \( n \) points such that no three of them are collinear. For each integer \( j \) such that \( 1 \leq j \leq n - 1 \) let \( \mathcal{H}_{2j-1}, \mathcal{H}_{2j} \) be the closed half-planes with common edge the line \( P_j P_{j+1} \), and \( \mathcal{H}_{2n-1}, \mathcal{H}_{2n} \) the closed half-planes with edge \( P_n P_1 \). Suppose that all the points \( P_k \) lie in \( \mathcal{H}_{2j-1} \) in each case. Then the intersection \( \bigcap_{j=1}^n \mathcal{H}_{2j-1} \) is called a **convex polygon.** The intersection of the corresponding open half-planes is called the **interior** of the convex polygon. The notation for convex quadrangles is extended to convex polygons in a straightforward way.

Consider a convex polygonal region with sides \([P_1, P_2], [P_2, P_3], \ldots, [P_n, P_1] \). Let a point \( U \) interior to the polygon be joined by segments to the vertices. Then

\[
\sum_{j=1}^{n-1} \Delta[U, P_j, P_{j+1}] + \Delta[U, P_n, P_1] = \sum_{j=2}^{n-1} \Delta[P_1, P_j, P_{j+1}]. \tag{5.6.1}
\]

**Proof.** CASE 1. We first take the case of a triangle so that \( n = 3 \). Now \([P_1, U] \) will meet \([P_2, P_3] \) in a point \( V \). Then by 5.6.1(i)

\[
\Delta[U, P_1, P_2] + \Delta[U, P_2, P_3] + \Delta[U, P_3, P_1] \\
= \Delta[U, P_1, P_2] + \{\Delta[U, P_2, V] + \Delta[U, V, P_3]\} + \Delta[U, P_3, P_1] \\
= \{\Delta[U, P_1, P_2] + \Delta[U, P_2, V]\} + \{\Delta[U, V, P_3] + \Delta[U, P_3, P_1]\} \\
= \Delta[P_1, P_2, V] + \Delta[V, P_3, P_1] = \Delta[P_1, P_2, P_3].
\]
CASE 2. Secondly we take the case of a convex quadrilateral so that \( n = 4 \). Suppose first that \( U \in [P_1, P_3] \). Then by 5.6.1(i) used twice,

\[
\{ \Delta[U, P_1, P_2] + \Delta[U, P_2, P_3] \} + \{ \Delta[U, P_3, P_4] + \Delta[U, P_4, P_1] \} \\
= \Delta[P_1, P_2, P_3] + \Delta[P_1, P_3, P_4].
\]

Suppose next that \( U \notin [P_1, P_3] \). Then \( U \) is interior to \([P_1, P_2, P_3] \) or \([P_1, P_3, P_4] \), say \( U \in [P_1, P_3, P_4] \).

We need to show that we have a convex quadrilateral \([P_1, P_2, P_3, U] \). Now \( U \in \mathcal{R}(P_1P_2P_3) \) for which \([P_1, P_3] \) is a cross-bar. Thus \([P_2, U] \) meets \([P_1, P_3] \) in a point \( T \). Now we cannot have \( U \in [P_2, T] \) as that would make \( U \in [P_1, P_2, P_3] \), nor can we have \( P_2 \in [T, U] \) as that would put \( U \) outside \( \mathcal{H}_1 \) and \( \mathcal{H}_3 \), so we must have \( T \in [P_2, U] \).

Then by 5.6.1(ii)

\[
\Delta[U, P_1, P_2] + \Delta[U, P_2, P_3] = \Delta[P_1, P_2, P_3] + \Delta[U, P_1, P_3],
\]

so

\[
\Delta[U, P_1, P_2] + \Delta[U, P_2, P_3] + \Delta[U, P_3, P_4] + \Delta[U, P_4, P_1] \\
= \Delta[P_1, P_2, P_3] + \{ \Delta[U, P_1, P_3] + \Delta[U, P_3, P_4] + \Delta[U, P_4, P_1] \} \\
= \Delta[P_1, P_2, P_3] + \Delta[P_1, P_3, P_4]
\]

by CASE 1.

CASE 3. We now suppose that the result holds, for some \( n \geq 4 \), for any convex polygonal region with \( n \) sides. Then for that \( n \) consider any convex polygonal region with \( n + 1 \) sides, \([P_1, P_2], [P_2, P_3], \ldots, [P_n, P_{n+1}], [P_{n+1}, P_1] \).

As \( n + 1 \geq 5 \), \([P_1, P_2, P_3] \) and \([P_1, P_{n+1}, P_1] \) have only \( P_1 \) in common, so \( U \) cannot be in both. For suppose that \( U \) is an interior point which is common to both. Then
The parallel axiom; Euclidean geometry

\[ P_1, U \text{ meets } P_2, P_3 \text{ at a point } V \neq P_2 \text{ so that } U \in [P_1, V]. \] Also \( P_1, U \text{ meets } P_{n-1}, P_n \) at a point \( W \neq P_n \) so that \( U \in [P_1, W] \). If we write \( l = P_1 U \) and have \( P_1 \leq l U \), then \( U \leq_l V, U \leq_l W \) and as \( V \leq_l W \) or \( W \leq_l V \) we have \( V \in [U, W] \) or \( W \in [U, V] \).

One possibility is that \( W = V \). We cannot have either \( P_{n-1} \) or \( P_n \) on \( P_2 P_3 \) as that would make three points \( P_k \) collinear. Then we have that \( V = W \in [P_{n-1}, P_n] \) and \( V \in P_2 P_3 \) so that \( P_{n-1} \) and \( P_n \) are on different sides of \( P_2 P_3 \), that is one is in \( \mathcal{H}_3 \) and the other is not, whereas all the vertices \( P_k \) are in \( \mathcal{H}_3 \). This contradiction implies that \( V \neq W \).

A second possibility is that \( V \in [U, W], V \neq W \). Then \( W \notin \mathcal{H}_3 \) whereas \( P_{n-1}, P_n \in \mathcal{H}_3 \) and as \( W \in [P_{n-1}, P_n] \subset \mathcal{H}_3 \) we have a contradiction.

A third and final possibility is that \( W \in [U, V], W \neq V \). Then \( V \notin \mathcal{H}_{2n-3} \) whereas \( P_2, P_3 \in \mathcal{H}_{2n-3} \) and as \( V \in [P_2, P_3] \subset \mathcal{H}_{2n-3} \) we have a contradiction again.

With this preparation suppose now that \( U \notin [P_1, P_2, P_3] \). By 5.6.1(ii)

\[ \Delta[U, P_1, P_2] + \Delta[U, P_2, P_3] = \Delta[P_1, P_2, P_3] + \Delta[U, P_1, P_3]. \]

Hence as \( U \) is interior to the polygon with \( n \) sides \([P_1, P_3], [P_3, P_4], \ldots, [P_n, P_{n+1}], [P_{n+1}, P_1] \),

\[
\sum_{j=1}^{n} \Delta[U, P_j, P_{j+1}] + \Delta[U, P_{n+1}, P_1]
= \Delta[P_1, P_2, P_3] + \Delta[U, P_1, P_3] + \sum_{j=3}^{n} \Delta[U, P_j, P_{j+1}] + \Delta[U, P_{n+1}, P_1]
= \Delta[P_1, P_2, P_3] + \sum_{j=3}^{n} \Delta[P_1, P_j, P_{j+1}] = \sum_{j=2}^{n} \Delta[P_1, P_j, P_{j+1}].
\]

If instead \( U \notin [P_1, P_n, P_{n+1}] \) we get the same conclusion by similar reasoning. The result now follows by induction on \( n \).

**Definition.** The area of the polygonal region in the present section is defined to be the sum of the areas of the triangles involved, as in (5.6.1).

**Exercises**

5.1 Opposite wedge-angles in a parallelogram have equal degree-measures.

5.2 If two adjacent sides of a rectangle have equal lengths, then all the sides have equal lengths. Such a rectangle is called a **square**.

5.3 If the diagonals of a parallelogram have equal lengths, it must be a rectangle.

5.4 If the diagonal lines of a rectangle are perpendicular, it must be a square.

5.5 Let \( A, B, C \) be non-collinear points and let \( P \in [A, B] \) and \( Q \in [A, C] \) be such that

\[
\frac{|A, P|}{|A, B|} = \frac{|A, Q|}{|A, C|}.
\]
Then $PQ \parallel BC$.

5.6 Let $AB \perp AC$ and let $D = \text{mp}(B, C)$. Prove that $|D, A| = |D, B| = |D, C|$.

5.7 Let $A, B, C$ be non-collinear points and for $A \in [B, P$ and $A \in [C, Q$ let $PQ \parallel BC$. Show that then

$$\frac{|A, P|}{|A, B|} = \frac{|A, Q|}{|A, C|}.$$  

5.8 Suppose that $A, B, C$ are non-collinear points with $|A, B| > |A, C|$ and let $D = \pi_{BC}(A)$. Prove that then

5.9 Suppose that $A, B, C$ are non-collinear points and $D$ is the mid-point of $B$ and $C$. Prove that then

[Hint. Consider the foot of the perpendicular from $A$ to $BC$.]

5.10 Show that the AAS-principle of congruence in Ex.4.2 can be deduced from 5.2.2 and the ASA-principle.

5.11 Show that the AAS-principle of congruence for right-angled triangles in Ex.4.3 can be deduced from Pythagoras’ theorem and the SSS-principle.

5.12 For $C \notin AB$, suppose that $m$ is the line through $C$ which is parallel to $AB$. Prove that for any point $D \notin AB$ the line $AD$ meets $m$ in a unique point $E$. When, additionally, $D \in \mathcal{N}(BAC)$ then $E$ is on $[A, D$ and is also on $m \cap \mathcal{N}(BAC)$.

5.13 In a triangle $[A, B, C]$, let $|A, B| > |A, C|$. Let $D \in [A, B$ be such that $|A, D| = |A, C|$. Prove that then

$$2|\angle BCD|^\circ = |\angle ACB|^\circ - |\angle CBA|^\circ.$$
6

Cartesian coordinates; applications

COMMENT. Hitherto we have confined ourselves to synthetic or pure geometrical arguments aided by a little algebra, and traditionally this is continued with. This is a difficult process because of the scarcity of manipulations, operations and transformations to aid us. The main difficulties in synthetic proofs are locational, to show that points are where the diagrams suggest they should be, and in making sure that all possible cases are covered.

For ease and efficiency we now introduce coordinates, and hence thoroughgoing algebraic methods. These not only enable us to deal with the concepts already introduced but also to elaborate on them in an advantageous way.

In Chapter 6 we do the basic coordinate geometry of lines, segments, half-lines and half-planes. The only use we make of angles here is to deal with perpendicularity.

6.1 FRAME OF REFERENCE, CARTESIAN COORDINATES

6.1.1 Definition. A couple or ordered pair $\mathcal{F} = ([O, I], [O, J])$ of half-lines such that $OI \perp OJ$, will be called a frame of reference for $\Pi$. With it, as standard notation, we shall associate the pair of closed half-planes $\mathcal{H}_1, \mathcal{H}_2$, with common edge $OI$, and with $J \in \mathcal{H}_1$, and the pair of closed half-planes $\mathcal{H}_3, \mathcal{H}_4$, with common edge $OJ$, and with $I \in \mathcal{H}_3$. We refer to $Q_1 = \mathcal{H}_1 \cap \mathcal{H}_3$, $Q_2 = \mathcal{H}_1 \cap \mathcal{H}_4$, $Q_3 = \mathcal{H}_2 \cap \mathcal{H}_4$ and $Q_4 = \mathcal{H}_2 \cap \mathcal{H}_3$, respectively, as the first, second, third and fourth quadrants of $\mathcal{F}$. We refer to $OI$ and $OJ$ as the axes and to $O$ as the origin.

Given any point $Z$ in $\Pi$, (rectangular) Cartesian coordinates for $Z$ are defined as follows. Let $U$ be the foot of the perpendicular from $Z$ to $OI$ and $V$ the foot of the
perpendicular from \( Z \) to \( OJ \). We let

\[
x = \begin{cases} 
|O,U| & \text{if } Z \in \mathcal{H}_3, \\
-|O,U| & \text{if } Z \in \mathcal{H}_4,
\end{cases}
\]

and

\[
y = \begin{cases} 
|O,V| & \text{if } Z \in \mathcal{H}_1, \\
-|O,V| & \text{if } Z \in \mathcal{H}_2.
\end{cases}
\]

Then the ordered pair \((x, y)\) are called **Cartesian coordinates** for \( Z \), relative to \( F \). We denote this in symbols by \( Z \equiv F(x, y) \), but when \( F \) is fixed and can be understood, we relax this notation to \( Z \equiv (x, y) \).

**Cartesian coordinates have the following properties:-**

(i) If \( Z \in \mathcal{D}_1 \), then \( x \geq 0, y \geq 0 \); if \( Z \in \mathcal{D}_2 \), then \( x \leq 0, y \geq 0 \); if \( Z \in \mathcal{D}_3 \), then \( x \leq 0, y \leq 0 \); if \( Z \in \mathcal{D}_4 \), then \( x \geq 0, y \leq 0 \).

(ii) If \( Z_1 \equiv (x_1, y_1), Z_2 \equiv (x_2, y_2) \) and

\[
U_1 = \pi_{OJ}(Z_1), \ V_1 = \pi_{OJ}(Z_1), \ U_2 = \pi_{OI}(Z_2), \ V_2 = \pi_{OI}(Z_2),
\]

then \( |U_1, U_2| = \pm(x_2 - x_1), \ |V_1, V_2| = \pm(y_2 - y_1) \).

(iii) If \( Z_1 \equiv (x_1, y_1), Z_2 \equiv (x_2, y_2) \), then

\[
|Z_1, Z_2| = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}.
\]

(iv) If \( Z_1 \equiv (x_1, y_1), Z_2 \equiv (x_2, y_2) \) and \( Z_3 \equiv (x_3, y_3) \) where

\[
x_3 = \frac{1}{2}(x_1 + x_2), \ y_3 = \frac{1}{2}(y_1 + y_2),
\]

then \( Z_3 = mp(Z_1, Z_2) \).

(v) Let \( \leq_l \) be the natural order on \( l = OI \) under which \( O \leq_l I \). If \( x_1 < x_2 \), \( U_1 \equiv (x_1, 0) \) and \( U_2 \equiv (x_2, 0) \), then \( U_1 \leq_l U_2 \).
Proof.
(i) This is clear from the definition of coordinates.
(ii) For if $Z_1, Z_2 \in \mathcal{H}_3$ we have

$$|O, U_2| = x_1, \quad |O, U_2| = x_2,$$

and so as $U_1, U_2 \in [O, I]$,

$$|U_1, U_2| = \pm (x_2 - x_1)$$

according as $U_1 \in [O, U_2]$ or $U_2 \in [O, U_1]$. Similarly if $Z_1, Z_2 \in \mathcal{H}_4$, we have

$$|O, U_1| = -x_1, \quad |O, U_2| = -x_2$$

and

$$|U_1, U_2| = \pm [-x_2 - (-x_1)]$$

according as $U_1 \in [O, U_2]$ or $U_2 \in [O, U_1]$. Finally if $Z_1 \in \mathcal{H}_3$, $Z_2 \in \mathcal{H}_4$ then

$$|O, U_1| = x_1, \quad |O, U_2| = -x_2$$

and $O \in [U_1, U_2]$ so that

$$|U_1, U_2| = x_1 + (-x_2);$$

similarly if $Z_1 \in \mathcal{H}_4, Z_2 \in \mathcal{H}_3$.

That $|V_1, V_2| = \pm (y_2 - y_1)$ can be shown in the same way.

(iii) Now the lines through $Z_1$ parallel to $O \ell$ and through $Z_2$ parallel to $O \ell$ are perpendicular to each other, and so meet in a unique point $Z_4$. Clearly $\pi_{O\ell}(Z_2) = \pi_{O\ell}(Z_2) = U_2$ so $Z_2$ and $Z_4$ have the same first coordinate, $x_2$; $\pi_{O\ell}(Z_4) = \pi_{O\ell}(Z_1) = V_1$ so $Z_1$ and $Z_4$ have the same second coordinate, $y_1$. Thus $Z_4$ has coordinates $(x_2, y_1)$. If the points $Z_1, Z_2, Z_4$ are not collinear, then by Pythagoras’ theorem

$$|Z_1, Z_2|^2 = |Z_1, Z_4|^2 + |Z_4, Z_2|^2;$$

if they are collinear we must have $Z_1 = Z_4$ or $Z_2 = Z_4$ and this identity is trivially true. But $|Z_1, Z_4| = |U_1, U_2|$ as $[Z_1, Z_4, U_2, U_1]$ is a rectangle, or else $Z_1 = Z_4$ and $U_1 = U_2$, or $Z_1 = U_1, Z_4 = U_2$. Similarly $|Z_2, Z_4| = |V_1, V_2|$. Thus we have the distance formula

$$|Z_1, Z_2|^2 = |U_1, U_2|^2 + |V_1, V_2|^2$$

$$= (x_2 - x_1)^2 + (y_2 - y_1)^2,$$

which expresses the distance $|Z_1, Z_2|$ in terms of the coordinates of $Z_1$ and $Z_2$.

(iv) If $Z_1 = Z_2$, then $x_2 = x_1, y_2 = y_1$ so that $x_3 = x_1, y_3 = y_1$. Thus $Z_3 = Z_1 = mp(Z_1, Z_1)$, as required.

Suppose then that $Z_1 \neq Z_2$. Note that

$$|Z_1, Z_3|^2 = \left[\frac{x_1 + x_2}{2} - x_1\right]^2 + \left[\frac{y_1 + y_2}{2} - y_1\right]^2 = \left[\frac{x_2 - x_1}{2}\right]^2 + \left[\frac{y_2 - y_1}{2}\right]^2.$$
and so \(|Z_1, Z_3| = \frac{1}{2}|Z_1, Z_2|\). Similarly
\[ |Z_3, Z_2|^2 = \left[ \frac{x_1 + x_2}{2} - x_2 \right]^2 + \left[ \frac{y_1 + y_2}{2} - y_2 \right]^2 = \left[ \frac{x_1 - x_2}{2} \right]^2 + \left[ \frac{y_1 - y_2}{2} \right]^2 \]
and so \(|Z_3, Z_2| = \frac{1}{2}|Z_1, Z_2|\). Then
\[ |Z_1, Z_3| + |Z_3, Z_2| = |Z_1, Z_2|. \]
It follows by 3.1.2 and 4.3.1 that \(Z_3 \in [Z_1, Z_2] \subset Z_1 Z_2\). As
\(|Z_1, Z_3| = |Z_3, Z_2|\) it then follows that \(Z_3 = \text{mp}(Z_1, Z_2)\).

(v) By 2.1.4 at least one of
\[
\begin{align*}
(a) & \quad O \in [U_1, U_2], \\
(b) & \quad U_1 \in [O, U_2], \\
(c) & \quad U_2 \in [O, U_1],
\end{align*}
\]
holds.

In (a), \(U_1 \) and \(U_2 \) are in different half-lines with end-point \(O \). We cannot have \(U_1 \in [O, I]\) as then we would have \(x_1 \geq 0, x_2 \leq 0\), a contradiction. Thus \(U_2 \in [O, I]\) so that \(U_1 \leq I, O \leq U_2\) and thus \(U_1 \leq U_2\).

In (b) we cannot have \(U_1 \leq I, O\). For then we would have \(U_2 \leq I, O\) and
\[ |O, U_1| = -x_1, \quad |O, U_2| = -x_2. \]
As \(U_1 \in [O, U_2]\) we have \(|O, U_1| \leq |O, U_2|\) which yields \(-x_1 \leq -x_2\) and so \(x_1 \geq x_2\), a contradiction. Hence \(O \leq U_1\) and so as \(U_1 \in [O, U_2]\), \(U_1 \leq U_2\).

In (c) we cannot have \(O \leq U_1\). For then we would have \(O \leq U_2\) and so
\[ |O, U_1| = x_1, \quad |O, U_2| = x_2. \]
As \(U_2 \in [O, U_1]\) we have \(|O, U_2| \leq |O, U_1|\), so that \(x_2 \leq x_1\), a contradiction. Hence \(U_1 \leq I, O\) so \(U_1 \leq U_2\).
6.2 ALGEBRAIC NOTE ON LINEAR EQUATIONS

6.2.1

It is convenient to note here some results on solutions of two simultaneous linear equations in two unknowns.

(a) If 
\[ a_{1,2}a_{2,2} - a_{1,2}a_{2,1} \neq 0, \]  
then the pair of simultaneous equations

\[ a_{1,1}x + a_{1,2}y = k_1, \]
\[ a_{2,1}x + a_{2,2}y = k_2, \]

has precisely one solution pair \((x,y)\), and that is given by

\[ (x,y) = \left( \frac{a_{2,2}k_1 - a_{1,2}k_2}{a_{1,1}a_{2,2} - a_{1,2}a_{2,1}}, \frac{a_{1,1}k_2 - a_{2,1}k_1}{a_{1,1}a_{2,2} - a_{1,2}a_{2,1}} \right). \]

(b) If

\[ (a_{1,1},a_{1,2}) \neq (0,0) \quad \text{and} \quad (a_{2,1},a_{2,2}) \neq (0,0), \]

and

\[ a_{1,1}a_{2,2} - a_{1,2}a_{2,1} = 0, \]

then there is some \( j \neq 0 \) such that

\[ a_{2,1} = ja_{1,1}, \quad a_{2,2} = ja_{1,2}. \]

(c) If (6.2.4) holds, then for the system (6.2.2) of simultaneous equations to have either no, or more than one, solution pair \((x,y)\) it is necessary and sufficient that (6.2.5) hold.

Note in particular that when (6.2.4) holds, for the pair of homogeneous linear equations

\[ a_{1,1}x + a_{1,2}y = 0, \]
\[ a_{2,1}x + a_{2,2}y = 0, \]

to have a solution \((x,y)\) other than the obvious one \((0,0)\), it is necessary and sufficient that (6.2.5) hold.
6.3 CARTESIAN EQUATION OF A LINE

6.3.1

Given any line \( l \in \Lambda \), there are numbers \( a, b \) and \( c \), with the case \( a = b = 0 \) excluded, such that \( Z \equiv (x, y) \in l \) if and only if

\[
ax + by + c = 0.
\]

**Proof.** Take any point \( Z_2 \equiv (x_2, y_2) \notin l \) and let \( Z_3 \equiv (x_3, y_3) = s_l(Z_2) \). Then \( Z_2 \neq Z_3 \). Now \( l \) is the perpendicular bisector of \( [Z_2, Z_3] \), so by 4.1.1 \( Z \in l \) if and only if \( |Z, Z_2| = |Z, Z_3| \). As these are both non-negative, this is the case if and only if \( |Z, Z_2|^2 = |Z, Z_3|^2 \). By 6.1.1 this happens if and only if

\[
(x - x_2)^2 + (y - y_2)^2 = (x - x_3)^2 + (y - y_3)^2.
\]

This simplifies to

\[
2(x_3 - x_2)x + 2(y_3 - y_2)y + x_2^2 + y_2^2 - x_3^2 - y_3^2 = 0.
\]

On writing

\[
a = 2(x_3 - x_2), \quad b = 2(y_3 - y_2), \quad c = x_2^2 + y_2^2 - x_3^2 - y_3^2,
\]

we see that \( Z \equiv (x, y) \in l \) if and only \( ax + by + c = 0 \). Now \( a = b = 0 \) corresponds to \( x_2 = x_3, y_2 = y_3 \), which is ruled out as \( Z_2 \neq Z_3 \).

**COROLLARY.** Let \( Z_0 \equiv (x_0, y_0), Z_1 \equiv (x_1, y_1) \) be distinct points and \( Z \equiv (x, y) \). Then \( Z \in Z_0Z_1 \) if and only if

\[
-(y_1 - y_0)(x - x_0) + (x_1 - x_0)(y - y_0) = 0.
\]

**Proof.** By the theorem, there exist numbers \( a, b, c \), with the case \( a = b = 0 \) excluded, such that \( Z \in Z_0Z_1 \) if and only if \( ax + by + c = 0 \). As \( Z_0, Z_1 \in Z_0Z_1 \) we then have

\[
ax_0 + by_0 + c = 0, \\
ax_1 + by_1 + c = 0.
\]

We subdivide into two cases as follows.

**CASE 1.** Let \( x_0 \neq x_1 \). We rewrite our equations as

\[
ax_1 + c = -by_1, \\
ax_0 + c = -by_0,
\]

and regard these as equations in the unknowns \( a \) and \( c \). As \( x_1 - x_0 \neq 0 \), we note that by 6.2.1 we must have

\[
a = \frac{-b(y_1 - y_0)}{x_1 - x_0}, \quad c = \frac{-b(x_1y_0 - x_0y_1)}{x_1 - x_0}.
\]
Note that \( b \neq 0 \), as \( b = 0 \) would imply \( a = 0 \) here. On inserting these values for \( a \) and \( c \) above we see that \( Z \in l \) if and only if
\[
\frac{-b(y_1 - y_0)}{x_1 - x_0}x + by + \frac{-b(x_1y_0 - x_0y_1)}{x_1 - x_0} = 0,
\]
and so as \( b/(x_1 - x_0) \neq 0 \), if and only if
\[
-(y_1 - y_0)x + (x_1 - x_0)y - x_1y_0 + x_0y_1 = 0.
\]
This is equivalent to the stated equation.

CASE 2. Let \( y_0 \neq y_1 \). We rewrite our equations as
\[
by_1 + c = -ax_1,
\]
\[
by_0 + c = -ax_0,
\]
and note that, as \( y_1 - y_0 \neq 0 \), by 6.2.1 we must have
\[
b = -\frac{a(x_1 - x_0)}{y_1 - y_0}, \quad c = \frac{-a(y_1x_0 - y_0x_1)}{y_1 - y_0}.
\]
Note that \( a \neq 0 \), as \( a = 0 \) would imply \( b = 0 \) here. On inserting these values for \( b \) and \( c \) above we see that \( Z \in l \) if and only if
\[
ax + -\frac{a(x_1 - x_0)}{y_1 - y_0}y + \frac{-a(y_1x_0 - y_0x_1)}{y_1 - y_0} = 0,
\]
and so as \(-a/(y_1 - y_0) \neq 0 \), if and only if
\[
-(y_1 - y_0)x + (x_1 - x_0)y - x_1y_0 + x_0y_1 = 0.
\]
This is equivalent to the stated equation.

Now either CASE 1 or CASE 2 (or both) must hold, as otherwise we have \( x_0 = x_1 \), \( y_0 = y_1 \) and so \( Z_0 = Z_1 \), contrary to what is given.

**Definition.** If \( l \in \Lambda \) and \( l = \{Z \equiv (x, y) : ax + by + c = 0\} \), we call \( ax + by + c = 0 \) a *Cartesian equation* of \( l \) relative to \( \mathcal{F} \), and we write \( l \equiv \mathcal{F} ax + by + c = 0 \). When \( \mathcal{F} \) can be understood we relax this to \( l \equiv ax + by + c = 0 \).

Let \( l \in \Lambda \) be a line, with Cartesian equation

(i) \( ax + by + c = 0 \).

Then \( l \) also has

(ii) \( a_1x + b_1y + c_1 = 0 \),

as an equation if and only if

(iii) \( a_1 = ja, \; b_1 = jb, \; c_1 = jc \).
for some \( j \neq 0 \).

**Proof.**

**Necessity.** Suppose first that \( l \) can be expressed in each of the forms (i) and (ii) above. We subdivide into four cases as follows.

**CASE 1.** Suppose that \( a \neq 0, b \neq 0 \) and \( c \neq 0 \). Then we note from (i) that the points \( A \equiv (-c/a,0) \) and \( B \equiv (0,-c/b) \) are in \( l \), and are in fact the only points of \( l \) in either \( OI \) or \( OJ \), as \( A \) is the only point with \( y = 0 \) and \( B \) is the only point with \( x = 0 \).

We now note that none of \( a_1, b_1, c_1 \) can be equal to \( 0 \). For if \( a_1 = 0 \), by (ii) we would have \( y = -c_1/b_1 \) for all points \( Z \) in \( l \); this would make \( l \) parallel to \( OI \) and give a contradiction. Similarly \( b_1 = 0 \) would imply that \( x = -c_1/a_1 \) for all points \( Z \) in \( l \), making \( l \) parallel to \( OJ \) and again giving a contradiction. Moreover if \( c_1 = 0 \), by (ii) we would have that \( O \in l \), again a contradiction.

We note from (ii) that the points \( A_1 \equiv (-c_1/a_1,0) \), \( B_1 \equiv (0,-c_1/b_1) \) are in \( l \) and are in fact the only points of \( l \) in either \( OI \) or \( OJ \). Thus we must have \( A_1 = A, B_1 = B \) and so

\[
-\frac{c_1}{a_1} = -\frac{c}{a}, \quad -\frac{c_1}{b_1} = -\frac{c}{b}.
\]

Thus

\[
\frac{a_1}{a} = \frac{b_1}{b} = \frac{c_1}{c},
\]

and if we denote the common value of these by \( j \), we have \( j \neq 0 \) and (iii).

**CASE 2.** Suppose that \( a = 0 \). Then \( b \neq 0 \) and by (i) for every \( Z \in l \) we have \( y = -c/b \), so that \( l \) contains \( B \) and is parallel to \( OI \); when \( c \neq 0 \), \( l \) has no point in common with \( OI \), and when \( c = 0 \), \( l \) coincides with \( OI \). Now we must have \( a_1 = 0 \), as otherwise \( l \) would meet \( OI \) in the unique point \( A_1 \), and that would give a contradiction. Then \( b_1 \neq 0 \) and for every \( Z \in l \) we have \( y = -c_1/b_1 \), so that \( l \) contains \( B_1 \) and is parallel to \( OI \). Thus we must have

\[
-\frac{c_1}{b_1} = -\frac{c}{b}.
\]

When \( c = 0 \), this implies that \( c_1 = 0 \), so that if we take \( j = b_1/b \), we have satisfied (iii). When \( c \neq 0 \), we must have that \( b_1/b = c_1/c \), and if we take \( j \) to be the common value of these we have (iii) again.

**CASE 3.** Suppose that \( b = 0 \). This is treated similarly to CASE 2.

**CASE 4.** Finally suppose that \( a \neq 0, b \neq 0 \) and \( c = 0 \). Then by (i) we see that \( O \in l \) and then by (ii) we must have \( c_1 = 0 \). We see from (i) that \( C \equiv (1,-a/b) \) is in \( l \), and on using this information in (ii) we find that \( a_1 + b_1(-a/b) = 0 \). This implies that \( a_1/a = b_1/b \), and if we take \( j \) to be the common value of these, we must have (iii). This establishes the necessity of (iii).

**Sufficiency** Suppose now that (iii) holds. Then \( a_1x + b_1y + c_1 = j(ax + by + c) \) and as \( j \neq 0 \) we have \( a_1x + b_1y + c_1 = 0 \) if and only if \( ax + by + c = 0 \).
6.4 PARAMETRIC EQUATIONS OF A LINE

6.4.1

Let \( l \) be a line with Cartesian equation \( ax + by + c = 0 \).

(i) If \( Z_0 \equiv (x_0, y_0) \) is in \( l \), then

\[
l = \{Z \equiv (x, y) : x = x_0 + bt, y = y_0 - at, \ (t \in \mathbb{R})\}.
\]

(ii) If \( Z_1 \equiv (x_1, y_1) = (x_0 + b, y_0 - a) \) and \( \leq_l \) is the natural order on \( l \) for which \( Z_0 \leq l Z_1 \), then for \( Z_2 \equiv (x_0 + bt_2, y_0 - at_2) \), \( Z_3 \equiv (x_0 + bt_3, y_0 - at_3) \) we have \( t_2 \leq t_3 \) if and only if \( Z_2 \leq_l Z_3 \).

(iii) If \( Z_1 \equiv (x_1, y_1) = (x_0 + b, y_0 - a) \), then

\[
[Z_0, Z_1] = \{Z \equiv (x, y) : x = x_0 + bt, y = y_0 - at, \ (0 \leq t \leq 1)\}.
\]

(iv) With \( Z_1 \) as in (ii),

\[
[Z_0, Z_1] = \{Z \equiv (x, y) : x = x_0 + bt, y = y_0 - at, \ (t \geq 0)\}.
\]

**Proof.**

(i) If \( Z \in l \) then \( ax + by + c = 0 \), \( ax_0 + by_0 + c = 0 \), so that

\[
b(y - y_0) = -a(x - x_0). \tag{6.4.1}
\]

When \( b \neq 0 \), let us define \( t \) by \( t = (x - x_0)/b \); then by (6.4.1) we must have, \( y - y_0 = -at \). Thus

\[
x = x_0 + bt, \ y = y_0 - at, \tag{6.4.2}
\]

for some \( t \in \mathbb{R} \).

When \( b = 0 \) then \( a \neq 0 \), and by (6.4.1) we must have \( x = x_0 \). If we define \( t \) by \( t = (y - y_0)/(-a) \), then we have (6.4.2) for some \( t \in \mathbb{R} \).

Conversely suppose that (6.4.2) holds for any \( t \in \mathbb{R} \). Then

\[
ax + by + c = a(x_0 + bt) + b(y_0 - at) + c = ax_0 + by_0 + c = 0.
\]

(ii) We first suppose that \( l \) is not perpendicular to \( m = OI \), so that \( b \neq 0 \). We recall that \( Z_0, Z_1 \) are distinct points on \( l \) for which \( Z_0 \leq l Z_1 \). Let \( \leq_m \) be the natural order on \( m \) for which \( O \leq_m l \). Let \( U_0 = \pi_m(Z_0) \), \( U_1 = \pi_m(Z_1) \) so that \( U_0 \equiv (x_0, 0) \), \( U_1 \equiv (x_0 + b, 0) \).

![Figure 6.4. Direct correspondence.](image)

![Indirect correspondence.](image)
If \( b > 0 \), then \( x_0 < x_0 + b \) and so by 6.1.1 \( U_0 \leq m U_1 \). In this case we say that the correspondence between \( \leq_l \) and \( \leq_m \) is **direct**.

If \( b < 0 \) then \( x_0 + b < x_0 \) and so \( U_1 \leq m U_0 \). In this case we say that the correspondence between \( \leq_l \) and \( \leq_m \) is **indirect**. In what follows we assume that \( b > 0 \) so that the correspondence between \( \leq_l \) and \( \leq_m \) is direct. The other case can be covered by replacing \( \leq_m \) by \( \geq_m \) in the following.

Suppose now that \( Z_2 \leq_l Z_0 \); we wish to show that \( U_2 \leq_m U_3 \) where \( U_2 = \pi_m(Z_2) \), \( U_3 = \pi_m(Z_3) \). We subdivide into three cases.

**CASE 1.** Suppose that \( Z_2 \leq_l Z_0 \). Then \( Z_2 \leq_l Z_0 \leq_l Z_1 \) so that \( Z_0 \in [Z_2, Z_1] \). Then by 4.3.2, \( U_0 \in [U_2, U_1] \). As \( U_0 \leq m U_1 \), we then have \( U_2 \leq m U_0 \). There are now two possibilities, that \( Z_3 \leq_l Z_0 \) or that \( Z_0 \leq_l Z_3 \). In the first of these subcases, \( Z_3 \in [Z_2, Z_0] \) so \( U_3 \in [U_2, U_0] \). As \( U_2 \leq m U_0 \) we then have \( U_2 \leq m U_3 \). In the second of these subcases we have \( Z_0 \in [Z_2, Z_3] \) so \( U_0 \in [U_2, U_3] \). As \( U_2 \leq m U_0 \) we have \( U_0 \leq m U_3 \) so \( U_2 \leq m U_3 \).

**CASE 2.** Suppose that \( Z_0 \leq_l Z_1 \leq_l Z_1 \). Then \( Z_2 \in [Z_0, Z_1] \) so \( U_2 \in [U_0, U_1] \). As \( U_0 \leq m U_1 \) then \( U_0 \leq m U_2 \leq m U_1 \). Now \( Z_2 \in [Z_0, Z_3] \) so \( U_2 \in [U_0, U_3] \). As \( U_0 \leq m U_2 \) it follows that \( U_2 \leq_m U_3 \).

**CASE 3.** Suppose that \( Z_1 \leq_l Z_2 \). Then \( Z_1 \in [Z_0, Z_2] \) so that \( U_1 \in [U_0, U_2] \). As \( U_0 \leq m U_1 \) we then have \( U_1 \leq m U_2 \). Then \( Z_2 \in [Z_1, Z_3] \) so \( U_2 \in [U_1, U_3] \). As \( U_1 \leq m U_2 \) we have \( U_2 \leq m U_3 \).

Now continuing with all three cases, we note that \( U_2 \equiv (x_0 + bt_2, 0) \), \( U_3 \equiv (x_0 + bt_3, 0) \) and as \( U_2 \leq m U_3 \) by 6.1.1 we have \( x_0 + bt_2 \leq x_0 + bt_3 \). As \( b > 0 \) this implies that \( t_2 \leq t_3 \).

We also have that \( t_2 \leq t_3 \) implies \( Z_2 \leq_l Z_3 \). For otherwise \( Z_3 \leq_l Z_2 \) and so by the above \( t_3 \leq t_2 \), which gives a contradiction unless \( Z_2 = Z_3 \).

When \( l \) is perpendicular to \( OI \) we use \( \pi_{OJ} \) instead of \( \pi_m \). By a similar argument we reach the same conclusion.

(iii) This follows directly from (ii) of the present theorem. It can also be proved as follows. Note that in (6.4.2) \( t = 0 \) gives \( Z_0 \) and \( t = 1 \) gives \( Z_1 \). Then for \( Z \equiv (x, y) \)
with \( x \) and \( y \) as in (6.4.2), by 6.1.1 we have

\[
|Z_0, Z| = \sqrt{(x-x_0)^2 + (y-y_0)^2} = \sqrt{(bt)^2 + (-at)^2} = |t|\sqrt{b^2 + a^2},
\]
\[
|Z_1, Z| = \sqrt{(bt-t)^2 + (a-at)^2} = \sqrt{(t-1)^2(b^2 + a^2)} = |t-1|\sqrt{b^2 + a^2},
\]
\[
|Z_0, Z_1| = \sqrt{b^2 + (-a)^2} = \sqrt{b^2 + a^2}.
\]

Thus when \( t < 0 \),

\[
|Z_0, Z| = (-t)\sqrt{b^2 + a^2}, \quad |Z_1, Z| = (1-t)\sqrt{b^2 + a^2},
\]

and so \( |Z, Z_0| + |Z_0, Z_1| = |Z, Z_1| \); thus by 3.1.2 and (i) above, \( Z_0 \in [Z, Z_1], \)
\( Z_0 \not\equiv Z, Z \not\equiv Z_1 \).

When \( 0 \leq t \leq 1 \),

\[
|Z_0, Z| = t\sqrt{b^2 + a^2}, \quad |Z, Z_1| = (1-t)\sqrt{b^2 + a^2},
\]

and so \( |Z_0, Z| + |Z, Z_1| = |Z_0, Z_1| \); thus \( Z \in [Z_0, Z_1] \).

When \( t > 1 \),

\[
|Z_0, Z| = t\sqrt{b^2 + a^2}, \quad |Z_1, Z| = (t-1)\sqrt{b^2 + a^2},
\]

and so \( |Z_0, Z_1| + |Z_1, Z| = |Z_0, Z| \); thus \( Z_1 \in [Z_0, Z] \) and \( Z \not\equiv Z_0, Z \not\equiv Z_1 \).

These combined show that the values of \( t \) for which \( 0 \leq t \leq 1 \) are those for which
\( Z \in [Z_0, Z_1] \).

(iv) This follows directly from (ii) of the present theorem. It can also be proved as
follows. As in the proof of (iii) above, we see that the values of \( t \) for which \( t \geq 0 \) are
those for which \( Z \in [Z_0, Z_1] \).

**COROLLARY.** Let \( Z_0 \equiv (x_0, y_0) \) and \( Z_1 \equiv (x_1, y_1) \) be distinct points. Then the fol-

(i)

\[
Z_0Z_1 = \{Z \equiv (x, y) : x = x_0 + t(x_1 - x_0), \quad y = y_0 + t(y_1 - y_0), \quad t \in \mathbb{R}\}.
\]

(ii) Let \( \leq_l \) be the natural order on \( l = Z_0Z_1 \) for which \( Z_0 \leq_l Z_1 \). Let

\[
Z_2 \equiv (x_0 + t_2(x_1 - x_0), y_0 + t_2(y_1 - y_0)),
\]
\[
Z_3 \equiv (x_0 + t_3(x_1 - x_0), y_0 + t_3(y_1 - y_0)).
\]

Then we have \( t_2 \leq t_3 \) if and only if \( Z_2 \leq_l Z_3 \).

(iii)

\[
[Z_0, Z_1] = \{Z \equiv (x, y) : x = x_0 + t(x_1 - x_0), \quad y = y_0 + t(y_1 - y_0), \quad 0 \leq t \leq 1\}.
\]
(iv) \[ Z_0, Z_1 = \{ Z \equiv (x, y) : x = x_0 + t(x_1 - x_0), \ y = y_0 + t(y_1 - y_0), \ t \geq 0 \}. \]

**Proof.** By 6.3.1, in the above we can take \( a = -(y_1 - y_0), \ b = x_1 - x_0 \) and the conclusions follow immediately.

**NOTE.** We refer to \( x = x_0 + bt, \ y = y_0 - at, \ (t \in \mathbb{R}) \) in 6.4.1 as **parametric equations** of the line \( l \), and \( t \) as the **parameter** of the point \( Z \equiv (x, y) \).

### 6.5 PERPENDICULARITY AND PARALLELISM OF LINES

#### 6.5.1

Let \( l \equiv ax + by + c = 0, \ m \equiv a_1x + b_1y + c_1 = 0 \).

(i) Then \( l \perp m \) if and only if

\[ aa_1 + bb_1 = 0. \] \hspace{1cm} (6.5.1)

(ii) Also \( l \parallel m \) if and only if

\[ ab_1 - a_1b = 0. \] \hspace{1cm} (6.5.2)

**Proof.**

(i) Suppose that \( l \perp m \). Then \( l \) meets \( m \) in a unique point which we denote by \( Z_0 \). By 6.4.1 \( Z_1 \equiv (x_0 + b, y_0 - a) \) is a point of \( l \) and similarly \( Z_2 \equiv (x_0 + b_1, y_0 - a_1) \) is a point of \( m \). Now by Pythagoras’ theorem \( |Z_0, Z_1|^2 + |Z_0, Z_2|^2 = |Z_1, Z_2|^2 \) and so by 6.1.1

\[ b^2 + (-a)^2 + b_1^2 + (-a_1)^2 = (b - b_1)^2 + (a - a_1)^2. \]

This simplifies to (6.5.1).

Conversely suppose that (6.5.1) holds. Then we cannot have (6.5.2) as well. For if we did, on multiplying (6.5.1) by \( a \) and (6.5.2) by \( b \) we would find that

\[ a^2a_1 + abb_1 = 0, \ -b^2a_1 + abb_1 = 0, \]

so that \( (a^2 + b^2)a_1 = 0 \), and hence as \((a, b) \neq (0, 0), \ a_1 = 0 \). Similarly

\[ ab_1 + b^2b_1 = 0, \ -aba_1 + a^2b_1 = 0, \]

so that \( b_1 = 0 \) as well, giving a contradiction. We now search for a point of intersection of \( l \) and \( m \), and so consider solving for \((x, y)\) the simultaneous equations

\[ ax + by = -c, \ a_1x + b_1y = -c_1. \]
As $ab_1 - a_1b \neq 0$, by 6.2.1 these will have a unique solution, yielding a point which we shall denote by $Z_0 \equiv (x_0, y_0)$. Then by 6.4.1

\[ l = \{ Z \equiv (x, y) : x = x_0 + bt, y = y_0 - at, t \in \mathbb{R} \}, \]
\[ m = \{ Z \equiv (x, y) : x = x_0 + b_1 t, y = y_0 - a_1 t, t \in \mathbb{R} \}. \]

We choose $Z_1 \in l$, $Z_2 \in m$ as above, and from (6.5.1) find that $|Z_0, Z_1|^2 + |Z_0, Z_2|^2 = |Z_1, Z_2|^2$. By 6.4.1 we can conclude that $l \perp m$.

(ii) By 6.2.1 the equations $ax + by + c = 0$, $a_1 x + b_1 y + c = 0$ have either no solution or more than one if and only if (6.5.2) holds.

Alternatively, by (i) above we have $l \parallel m$ if and only if there is some $(a_2, b_2) \neq (0, 0)$ such that

\[ aa_2 + bb_2 = 0, \ a_1 a_2 + b_1 b_2 = 0. \]

But the equations

\[ au + bv = 0, \ a_1 u + b_1 v = 0, \]

have a solution $(u, v)$ other than $(0, 0)$ if and only if $ab_1 - a_1b = 0$. Thus (6.5.2) is a condition for $l$ and $m$ to be parallel.

**COROLLARY.**

(i) The lines $Z_1Z_2$ and $Z_3Z_4$ are perpendicular if and only if

\[ (y_2 - y_1)(y_4 - y_3) + (x_2 - x_1)(x_4 - x_3) = 0. \]

(ii) These lines are parallel if and only if

\[ -(y_2 - y_1)(x_4 - x_3) + (y_4 - y_3)(x_2 - x_1) = 0. \]

### 6.6 PROJECTION AND AXIAL SYMMETRY

#### 6.6.1

Let $l \equiv ax + by + c = 0$ and $Z_0 \equiv (x_0, y_0)$. Then

(i)

\[ |Z_0, \pi_l(Z_0)| = \frac{|ax_0 + by_0 + c|}{\sqrt{a^2 + b^2}}. \]

(ii)

\[ \pi_l(Z_0) \equiv \left( x_0 - \frac{a}{a^2 + b^2}(ax_0 + by_0 + c), \ y_0 - \frac{b}{a^2 + b^2}(ax_0 + by_0 + c) \right). \]
\[
s_i(Z_0) \equiv (x_0 - \frac{2a}{a^2 + b^2}(ax_0 + by_0 + c), \ y_0 - \frac{2b}{a^2 + b^2}(ax_0 + by_0 + c)).
\]

**Proof.** Let \( m \) be the line such that \( l \perp m \) and \( Z_0 \in m \). Then as \( l \perp m \), by 6.5.1 we will have \( m \equiv -bx + ay + c_1 = 0 \) for some \( c_1 \), and as \( Z_0 \in m \) we have \( c_1 = bx_0 - ay_0 \).

To find the coordinates \((x, y)\) of \( \pi_l(Z_0) \) we need to solve simultaneously the equations
\[
ax + by = -c, \quad -bx + ay = -bx_0 + ay_0.
\]
As for (i) we shall then go on to apply 6.1.1 it is \((x - x_0)^2\) and \((y - y_0)^2\) that we shall actually use, and it is easier to work directly with these. We rewrite the equations as
\[
ax(x - x_0) + by(y - y_0) = -(ax_0 + by_0 + c),
\]
\[
-b(x - x_0) + a(y - y_0) = 0.
\]

Now on squaring each of these and adding, we find that
\[
(a^2 + b^2)[(x - x_0)^2 + (y - y_0)^2] = (ax_0 + by_0 + c)^2.
\]

The conclusion (i) now readily follows.

For (ii) we solve these equations, obtaining
\[
x - x_0 = -\frac{a}{a^2 + b^2}(ax_0 + by_0 + c), \quad y - y_0 = -\frac{b}{a^2 + b^2}(ax_0 + by_0 + c)).
\]

For (iii) we recall that if \( s_l(Z_0) \equiv (x_1, y_1) \) and \( \pi_l(Z_0) \equiv (x_2, y_2) \), then as \( mp(Z_0, s_l(Z_0)) = \pi_l(Z_0) \) we have \( x_1 + x_0 = 2x_2, \ y_1 + y_0 = 2y_2 \). Now \( x_2 \) and \( y_2 \) are given by (ii) of the present theorem, and the result follows.

### 6.6.2 Formula for area of a triangle

Let \( Z_1 \equiv \mathcal{F} (x_1, y_1), Z_2 \equiv \mathcal{F} (x_2, y_2) \) and \( Z_3 \equiv \mathcal{F} (x_3, y_3) \) be non-collinear points. Then the area \( \Delta[Z_1, Z_2, Z_3] \) is equal to \( |\delta_{\mathcal{F}}(Z_1, Z_2, Z_3)| \) where
\[
\delta_{\mathcal{F}}(Z_1, Z_2, Z_3) = \frac{1}{2}[x_1(y_2 - y_3) - y_1(x_2 - x_3) + x_2y_3 - x_3y_2]
\]
\[
= \frac{1}{2} \det \begin{pmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{pmatrix}.
\]

**Proof.** By 6.3.1 \( Z_2Z_3 \equiv -(y_3 - y_2)(x - x_2) + (x_3 \ - x_2)(y - y_2) = 0 \), so by 6.6.1
\[
[Z_1, \pi_{Z_2Z_3}(Z_1)] \quad \text{is equal to}
\]
\[
\frac{|-(y_3 - y_2)(x_3 - x_2) + (x_3 - x_2)(y_3 - y_2)|}{\sqrt{(y_3 - y_2)^2 + (x_3 - x_2)^2}}.
\]
But
\[
\Delta[Z_1, Z_2, Z_3] = \frac{1}{2} |Z_2, Z_3||Z_1, \pi_{Z_2Z_3}(Z_1)|, \quad \text{and the denominator above is equal to} \quad |Z_2, Z_3|. \quad \text{Hence the area is equal to half the numerator.}
\]
6.6.3 Inequalities for closed half-planes

Let \( l \equiv ax + by + c = 0 \). Then the sets

\[
\{ Z \equiv (x, y) : ax + by + c \leq 0 \}, \\
\{ Z \equiv (x, y) : ax + by + c \geq 0 \},
\]

are the closed half-planes with common edge \( l \).

**Proof.** Let \( Z_1 \equiv (x_1, y_1) \) be a point not in \( l \), and let \( s_l(Z_1) = Z_2 \equiv (x_2, y_2) \). Let \( Z \equiv (x, y) \). Then as in 6.3.1, \( Z \in l \) if and only if \( |Z, Z_1|^2 = |Z, Z_2|^2 \), and this occurs when \((x - x_1)^2 + (y - y_1)^2 = (x - x_2)^2 + (y - y_2)^2\), which simplifies to

\[ 2(x_2 - x_1)x + 2(y_2 - y_1)y + x_1^2 + y_1^2 - x_2^2 - y_2^2 = 0. \]

This is an equation for \( l \) and so by 6.3.1 there is some \( j \neq 0 \) such that

\[ ax + by + c = j \left[ 2(x_2 - x_1)x + 2(y_2 - y_1)y + x_1^2 + y_1^2 - x_2^2 - y_2^2 \right]. \]

By 4.3.4 the sets

\[
\{ Z \equiv (x, y) : 2(x_2 - x_1)x + 2(y_2 - y_1)y + x_1^2 + y_1^2 - x_2^2 - y_2^2 \leq 0 \}, \\
\{ Z \equiv (x, y) : 2(x_2 - x_1)x + 2(y_2 - y_1)y + x_1^2 + y_1^2 - x_2^2 - y_2^2 \geq 0 \},
\]

are the closed half-planes with edge \( l \), as they correspond to \(|Z, Z_1| \leq |Z, Z_2|\) and \(|Z, Z_1| \geq |Z, Z_2|\), respectively. But when \( j > 0 \), (6.6.1) and (6.6.3) coincide as do (6.6.2) and (6.6.4), while when \( j < 0 \), (6.6.1) and (6.6.4) coincide as do (6.6.2) and (6.6.3).

6.7 COORDINATE TREATMENT OF HARMONIC RANGES

6.7.1 New parametrisation of a line

As in 6.4.1, if \( Z_1 \equiv (x_1, y_1), Z_2 \equiv (x_2, y_2), Z \equiv (x, y) \) where \( x = x_1 + t(x_2 - x_1), y = y_1 + t(y_2 - y_1) \), then \( Z \in Z_1Z_2 \) and

\[
|Z_1, Z|^2 = [t(y_2 - y_1)]^2 + [t(y_2 - y_1)]^2 = t^2|Z_1, Z_2|^2, \\
|Z, Z_2|^2 = [(1 - t)(x_2 - x_1)]^2 + [(1 - t)(y_2 - y_1)]^2 = (1 - t)^2|Z_1, Z_2|^2, \\
\frac{|Z_1, Z|}{|Z, Z_2|} = \left| \frac{t}{1 - t} \right|. 
\]

Accordingly, if we write \( \frac{t}{1 - t} = \lambda \) where \( \lambda \neq 0 \) and so have \( t = \frac{\lambda}{1 + \lambda} \), we have

\[
\frac{|Z_1, Z|}{|Z, Z_2|} = |\lambda|.
\]
Thus \( Z \) divides \((Z_1, Z_2)\) in the ratio \(|\lambda| : 1\).

Changing our notation slightly, if we denote by \( Z_3 \equiv (x_3, y_3) \) the point with

\[
x_3 = x_1 + \frac{\lambda}{1+\lambda}(x_2 - x_1) = \frac{1}{1+\lambda}x_1 + \frac{\lambda}{1+\lambda}x_2;
\]
\[
y_3 = y_1 + \frac{\lambda}{1+\lambda}(y_2 - y_1) = \frac{1}{1+\lambda}y_1 + \frac{\lambda}{1+\lambda}y_2;
\]

then \( Z_3 \) divides \((Z_1, Z_2)\) in the ratio \(|\lambda| : 1\). Consequently if we denote by \( Z_4 \equiv (x_4, y_4) \) the point with

\[
x_4 = \frac{1}{1+\lambda'}x_1 + \frac{\lambda'}{1+\lambda'}x_2, \quad y_4 = \frac{1}{1+\lambda'}y_1 + \frac{\lambda'}{1+\lambda'}y_2,
\]

where \( \lambda' = -\lambda \), so that

\[
x_4 = \frac{1}{1-\lambda}x_1 - \frac{\lambda}{1-\lambda}x_2, \quad y_4 = \frac{1}{1-\lambda}y_1 - \frac{\lambda}{1-\lambda}y_2,
\]

then \( Z_4 \) also divides \((Z_1, Z_2)\) in the ratio \(|-\lambda| : 1 = |\lambda| : 1\).

Now \( \lambda = \frac{t}{1-t} \) and if we write \( -\lambda = \frac{s}{1-s} \) we have \( Z_4 \) in the original format,

\[
x_4 = x_1 + s(x_2 - x_1), \quad y_4 = y_1 + s(y_2 - y_1).
\]

Then

\[
\frac{t}{1-t} = -\frac{s}{1-s}
\]

so that

\[
s = \frac{\frac{1}{2}t}{t - \frac{1}{2}}.
\]

Thus

\[
s - \frac{1}{2} = \frac{\frac{1}{2}t}{t - \frac{1}{2}} - \frac{1}{2} = \frac{\frac{1}{2}t - \frac{1}{2}t + \frac{1}{4}}{t - \frac{1}{2}} = \frac{\frac{1}{4}}{t - \frac{1}{2}}.
\]

Hence

\[
\left(s - \frac{1}{2}\right)\left(t - \frac{1}{2}\right) = \frac{1}{4}, \quad \left|\left(s - \frac{1}{2}\right)(t - \frac{1}{2})\right| = \frac{1}{4}. \quad (6.7.1)
\]

Then we have three possibilities,

(a) \(|t - \frac{1}{2}| < \frac{1}{2}, \quad |s - \frac{1}{2}| > \frac{1}{2} , \)

(b) \(|s - \frac{1}{2}| < \frac{1}{2}, \quad |t - \frac{1}{2}| > \frac{1}{2} , \)

(c) \(|s - \frac{1}{2}| = \frac{1}{2}, \quad |t - \frac{1}{2}| = \frac{1}{2} , \)

In (a) we have \(-\frac{1}{2} < t - \frac{1}{2} < \frac{1}{2} \) and either \(s - \frac{1}{2} < -\frac{1}{2} \) or \(s - \frac{1}{2} > \frac{1}{2} \). Hence \(0 < t < 1\) and either \(s < 0\) or \(s > 1\). It follows that \( Z_3 \in [Z_1, Z_2], Z_4 \notin [Z_1, Z_2]\).

The situation in (b) is like that in (a) with the roles of \( t \) and \( s \), and so of \( Z_3 \) and \( Z_4 \) interchanged.
In (c) \(-\frac{1}{2} = t - \frac{1}{2}\) or \(t - \frac{1}{2} = \frac{1}{2}\), so either \(t = 0\) or \(t = 1\). Similarly either \(s = 0\) or \(s = 1\). We rule out the case of \(t = 1\) as then \(\lambda\) would be undefined, and we rule out the case of \(s = 1\) as then \(-\lambda\) would be undefined. What remains is \(t = s = 0\) and we excluded this by taking \(\lambda \neq 0\); it would imply that \(Z_3 = Z_4 = Z_1\).

Thus just one of \(Z_3, Z_4\) is in the segment \([Z_1, Z_2]\) and the other is on the line \(Z_1Z_2\) but outside this segment. Hence \(Z_3\) and \(Z_4\) divide \(\{Z_1, Z_2\}\) internally and externally in the same ratio. We recall that we then call \((Z_1, Z_2, Z_3, Z_4)\) a harmonic range.

We note above that there can be no solution for \(s\) if \(t = \frac{1}{2}\); thus there is no corresponding \(Z_4\) when \(Z_3\) is the mid-point \(Z_0\) of \(Z_1\) and \(Z_2\). Similarly there can be no solution for \(t\) if \(s = \frac{1}{2}\); thus there is no corresponding \(Z_3\) when \(Z_4\) is \(Z_0\).

### 6.7.2 Interchange of pairs of points

If the points \(Z_3\) and \(Z_4\) divide \(\{Z_1, Z_2\}\) internally and externally in the same ratio, then it turns out that the points \(Z_1\) and \(Z_2\) also divide \(\{Z_3, Z_4\}\) internally and externally in the same ratio.

**Proof.** For we had

\[
\begin{align*}
x_3 &= \frac{1}{1+\lambda}x_1 + \frac{\lambda}{1+\lambda}x_2, \\
x_4 &= \frac{1}{1-\lambda}x_1 - \frac{\lambda}{1-\lambda}x_2,
\end{align*}
\]

\[
\begin{align*}
y_3 &= \frac{1}{1+\lambda}y_1 + \frac{\lambda}{1+\lambda}y_2, \\
y_4 &= \frac{1}{1-\lambda}y_1 - \frac{\lambda}{1-\lambda}y_2.
\end{align*}
\]

Then

\[
\begin{align*}
(1 + \lambda)x_3 &= x_1 + \lambda x_2, \\
(1 - \lambda)x_4 &= x_1 - \lambda x_2.
\end{align*}
\]

By addition and subtraction, we find that

\[
\begin{align*}
x_1 &= \frac{1+\lambda}{2}x_3 + \frac{1-\lambda}{2}x_4, \\
x_2 &= \frac{1+\lambda}{2\lambda}x_3 + \frac{\lambda-1}{2\lambda}x_4,
\end{align*}
\]

and by a similar argument,

\[
\begin{align*}
y_1 &= \frac{1+\lambda}{2}y_3 + \frac{1-\lambda}{2}y_4, \\
y_2 &= \frac{1+\lambda}{2\lambda}y_3 + \frac{\lambda-1}{2\lambda}y_4.
\end{align*}
\]

If we define \(\mu\) by

\[
\frac{1}{1+\mu} = \frac{1+\lambda}{2},
\]

so that

\[
\mu = \frac{1-\lambda}{1+\lambda}, \quad \frac{\mu}{1+\mu} = \frac{1-\lambda}{2},
\]
then

\[ x_1 = \frac{1}{1+\mu} x_3 + \frac{\mu}{1+\mu} x_4, \quad y_1 = \frac{1}{1+\mu} y_3 + \frac{\mu}{1+\mu} y_4. \]

If we define \( \mu' \) by

\[ \frac{1}{1+\mu'} = \frac{1+\lambda}{2\lambda}, \]

so that

\[ \mu' = \frac{\lambda - 1}{1+\lambda}, \quad \frac{\mu'}{1+\mu'} = \frac{\lambda - 1}{2\lambda}, \]

then

\[ x_2 = \frac{1}{1+\mu'} x_3 + \frac{\mu'}{1+\mu'} x_4, \quad y_2 = \frac{1}{1+\mu'} y_3 + \frac{\mu'}{1+\mu'} y_4. \]

As \( \mu' = -\mu \), this shows that \( Z_1 \) and \( Z_2 \) divide \( \{Z_3, Z_4\} \) internally and externally in the same ratio.

### 6.7.3 Distances from mid-point

Let \( Z_0 \) be the mid-point of distinct points \( Z_1 \) and \( Z_2 \). Then points \( Z_3, Z_4 \in Z_1Z_2 \) divide \( \{Z_1, Z_2\} \) internally and externally in the same ratio if and only if \( Z_3 \) and \( Z_4 \) are on the one side of \( Z_0 \) on the line \( Z_1Z_2 \) and

\[ |Z_0, Z_3||Z_0, Z_4| = \frac{1}{2}|Z_1, Z_2|^2. \]

**Proof.** We have \( Z_0 \equiv (x_0, y_0) \) where \( x_0 = \frac{1}{2}(x_1 + x_2), \quad y_0 = \frac{1}{2}(y_1 + y_2) \). Then

\[ x_3 - x_0 = (t - \frac{1}{2})(x_2 - x_1), \quad y_3 - y_0 = (t - \frac{1}{2})(y_2 - y_1), \]

\[ x_4 - x_0 = (s - \frac{1}{2})(x_2 - x_1), \quad y_4 - y_0 = (s - \frac{1}{2})(y_2 - y_1), \]

and so

\[ |Z_0, Z_3||Z_0, Z_4| = |(t - \frac{1}{2})(s - \frac{1}{2})||Z_1, Z_2|^2. \]

By (6.7.1) \( Z_3, Z_4 \) divide \( \{Z_1, Z_2\} \) internally and externally in the same ratio if and only if \( (s - \frac{1}{2})(t - \frac{1}{2}) = \frac{1}{2} \). This is equivalent to having \( |(s - \frac{1}{2})(t - \frac{1}{2})| = \frac{1}{2} \) and \( (s - \frac{1}{2})(t - \frac{1}{2}) > 0 \). The latter is equivalent to having either \( s - \frac{1}{2} > 0 \) and \( t - \frac{1}{2} > 0 \), or \( s - \frac{1}{2} < 0 \) and \( t - \frac{1}{2} < 0 \), so that \( Z_3 \) and \( Z_4 \) are on the one side of \( Z_0 \) on the line \( Z_1Z_2 \).

### 6.7.4 Distances from end-point

Let \( \{Z_3, Z_4\} \) divide \( \{Z_1, Z_2\} \) internally and externally in the same ratio with \( Z_2 \in [Z_1, Z_4] \). Then

\[ \frac{1}{2} \left( \frac{1}{|Z_1, Z_3|} + \frac{1}{|Z_1, Z_4|} \right) = \frac{1}{|Z_1, Z_2|}. \]

**Proof.** We have as before

\[ x_3 = x_1 + \frac{\lambda}{1+\lambda}(x_2 - x_1), \quad y_3 = y_1 + \frac{\lambda}{1+\lambda}(y_2 - y_1), \]

\[ x_4 = x_1 + \frac{\lambda}{\lambda - 1}(x_2 - x_1), \quad y_4 = y_1 + \frac{\lambda}{\lambda - 1}(y_2 - y_1), \]

Now \( \lambda/(\lambda - 1) > 1 \) and so \( \lambda > 1 \). Hence \( \frac{1}{2} < \lambda/(\lambda + 1) < 1 \), and so \( Z_3 \in [Z_1, Z_2] \). Thus \( Z_2, Z_3 \) and \( Z_4 \) are on the one side of \( Z_1 \) on the line \( Z_1Z_2 \). Then

\[
\frac{|Z_1, Z_3|}{|Z_1, Z_2|} = \frac{\lambda}{\lambda + 1}, \quad \frac{|Z_1, Z_4|}{|Z_1, Z_2|} = \frac{\lambda}{\lambda - 1},
\]

so that

\[
\frac{|Z_1, Z_2|}{|Z_1, Z_3|} = \frac{\lambda + 1}{\lambda}, \quad \frac{|Z_1, Z_2|}{|Z_1, Z_4|} = \frac{\lambda - 1}{\lambda},
\]

and so

\[
\frac{|Z_1, Z_2|}{|Z_1, Z_3|} + \frac{|Z_1, Z_2|}{|Z_1, Z_4|} = \frac{\lambda + 1}{\lambda} + \frac{\lambda - 1}{\lambda} = 2.
\]

Hence

\[
\frac{1}{2} \left( \frac{1}{|Z_1, Z_3|} + \frac{1}{|Z_1, Z_4|} \right) = \frac{1}{|Z_1, Z_2|}.
\]

This is expressed by saying that \( |Z_1, Z_2| \) is the harmonic mean of \( |Z_1, Z_3| \) and \( |Z_1, Z_4| \).

### 6.7.5 Construction for a harmonic range

Let \( Z_1, Z_2, Z_3 \) be distinct collinear points with \( Z_3 \) not the mid-point of \( Z_1 \) and \( Z_2 \). Take any points \( W_1 \) and \( W_2 \), not on \( Z_1Z_2 \), so that \( Z_2 \) is the mid-point of \( W_1 \) and \( W_2 \). Let \( l \) be the line through \( Z_1 \) which is parallel to \( W_1W_2 \) and let \( W_3 \) be the point in which \( W_1Z_3 \) meets \( l \), with \( Z_4 \) the point in which \( W_2W_3 \) meets \( Z_1Z_2 \). Then \( (Z_1, Z_2, Z_3, Z_4) \) is a harmonic range.

**Proof.** Without loss of generality we may take the \( x \)-axis to be the line \( Z_1Z_2 \) and so take coordinates

\[
Z_1 \equiv (x_1, 0), \quad Z_2 \equiv (x_2, 0), \quad Z_3 \equiv (x_3, 0), \quad Z_4 \equiv (x_4, 0),
\]

and \( W_1 \equiv (u_1, v_1), \quad W_2 \equiv (2x_2 - u_1, -v_1) \). The lines \( l \) and \( W_1Z_3 \) have equations

\[
(u_1 - x_2)y = v_1(x - x_1), \quad (u_1 - x_3)y = v_1(x - x_3),
\]
respectively, and so \( W_3 \) has coordinates

\[
u_3 = \frac{x_3(u_1 - x_2) - x_1(u_1 - x_3)}{x_3 - x_2}, \quad v_3 = \frac{x_3 - x_1}{x_3 - x_2}.
\]

On forming the equation of \( W_2W_3 \) and finding where it meets \( Z_1Z_2 \) we obtain

\[
x_4 = \frac{-x_3(x_1 + x_2) + 2x_1x_2}{x_1 + x_2 - 2x_3},
\]

from which it follows that

\[
x_4 - x_1 = \frac{(x_1 - x_2)(x_3 - x_1)}{x_1 + x_2 - 2x_3}, \quad x_2 - x_4 = \frac{(x_1 - x_2)(x_3 - x_2)}{x_1 + x_2 - 2x_3}.
\]

From these we see that

\[
\frac{x_4 - x_1}{x_2 - x_4} = -\frac{x_3 - x_1}{x_2 - x_3}.
\]

### Exercises

6.1 Suppose that \( Z_1, Z_2, Z_3 \) are non-collinear points and \( Z_5 = mp\{Z_3, Z_1\} \), \( Z_6 = mp\{Z_1, Z_2\} \). Show that if \( |Z_2, Z_5| = |Z_3, Z_6| \), then \( |Z_3, Z_1| = |Z_1, Z_2| \). (Hint. Select a frame of reference to simplify the calculations).

6.2 Let \( l_1, l_2 \) be distinct intersecting lines and \( Z_0 \) a point not on either of them. Show that there are unique points \( Z_1 \in l_1 \), \( Z_2 \in l_2 \) such that \( Z_0 \) is the mid-point of \( Z_1 \) and \( Z_2 \).

6.3 Suppose that \( Z_1, Z_2, Z_3 \) are non-collinear points. Show that the points \( Z \equiv (x, y) \), the perpendicular distances from which to the lines \( Z_1Z_2 \), \( Z_1Z_3 \) are equal, are those the coordinates of which satisfy

\[
\frac{-(y_2 - y_1)(x - x_1) + (x_2 - x_1)(y - y_1)}{\sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}} \\
\pm \frac{-(y_3 - y_1)(x - x_1) + (x_3 - x_1)(y - y_1)}{\sqrt{(x_3 - x_1)^2 + (y_3 - y_1)^2}} = 0.
\]

Show that if \( x = (1 - t)x_2 + tx_3 \), \( y = (1 - t)y_2 + ty_3 \) then \( Z \) lies on the line with equation

\[
\frac{-(y_2 - y_1)(x - x_1) + (x_2 - x_1)(y - y_1)}{\sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}} \\
+ \frac{-(y_3 - y_1)(x - x_1) + (x_3 - x_1)(y - y_1)}{\sqrt{(x_3 - x_1)^2 + (y_3 - y_1)^2}} = 0,
\]

if and only

\[
t = \frac{|Z_1, Z_2|^2}{|Z_1, Z_2|^2 + |Z_2, Z_3|^2}.
\]

Deduce that this latter line is the mid-line of \( |Z_2Z_1Z_3| \).
6.4 If the fixed triangle \([Z_1, Z_2, Z_3]\) is isosceles, with \(|Z_1Z_2| = |Z_1Z_3|\), and \(Z\) is a variable point on the side \([Z_2, Z_3]\), show that the sum of the perpendicular distances from \(Z\) to the lines \(Z_1Z_2\) and \(Z_1Z_3\) is constant. [Hint. Select a frame of reference to simplify the calculations.]

6.5 Let \([A, B, C, D]\) be a parallelogram, \(E = \text{mp}\{C, D\}\), \(F = \text{mp}\{A, B\}\), and let \(AE\) and \(CF\) meet \(BD\) at \(G\) and \(H\), respectively. Prove that \(AE \parallel CF\) and \(|D, G| = |G, H| = |H, B|\).
This page intentionally left blank
Hitherto our sets have involved lines and half-planes, and specific subsets of these. Now we introduce circles and study their relationships to lines. We do not do this just to admire the circles, and to behold their striking properties of symmetry. They are the means by which we control angles, and simplify our work on them.

7.1 INTERSECTION OF A LINE AND A CIRCLE

7.1.1

**Definition.** If \( O \) is any point of the plane \( \Pi \) and \( k \) is any positive real number, we call the set \( \mathcal{C}(O;k) \) of all points \( X \) in \( \Pi \) which are at a distance \( k \) from \( O \), i.e. \( \mathcal{C}(O;k) = \{X \in \Pi : |O,X| = k\} \), the *circle* with *centre* \( O \) and *length of radius* \( k \). If \( X \in \mathcal{C}(O;k) \) the segment \([O,X]\) is called a *radius* of the circle. Any point \( U \) such that \( |O,U| < k \) is said to be an *interior point* for this circle. Any point \( V \) such that \( |O,V| > k \) is said to be an *exterior point* for this circle.

For every circle \( \mathcal{C}(O;k) \) and line \( l \), one of the following holds:-

(i) \( l \cap \mathcal{C}(O;k) = \{P\} \) for some point \( P \), in which case every point of \( l \setminus \{P\} \) is exterior to the circle.

(ii) \( l \cap \mathcal{C}(O;k) = \{P,Q\} \) for some points \( P \) and \( Q \), with \( P \neq Q \), in which case every point of \([P,Q] \setminus \{P,Q\} \) is interior to the circle, and every point of \( PQ \setminus [P,Q] \) is exterior to the circle.

(iii) \( l \cap \mathcal{C}(O;k) = \emptyset \), in which case every point of \( l \) is exterior to the circle.

**Proof.** Let \( M = \pi_l(O) \), and let \( m \) be the line which contains \( M \) and is perpendicular to \( l \), so that \( O \in m \).
(i) Suppose that $|O,M| = k$, so that $M$ is a point of the circle. We write $P = M$. Then $P \in l$, $P \in \mathcal{C}(O;k)$ and $OP \perp l$. Thus if $V$ is any point of $l$, other than $P$, by 4.3.1 we have $|O,V| > |O,P| = k$. Hence $V$ is exterior to the circle, and so there is no point common to $l$ and the circle except $P$.

(ii) Suppose that $|O,M| < k$, so that $M$ is interior to the circle. Then $k^2 - |O,M|^2 > 0$ so that its square root can be extracted as a positive real number. By $A_4(\text{iv})$ choose $P \in l$ so that $|M,P| = \sqrt{k^2 - |O,M|^2}$. There is also a point $Q \in l$ on the other side of $M$ from $P$ and such that $|M,Q| = |M,P|$. Clearly $M$ is the mid-point of $P$ and $Q$.

When $M = O$, this gives $|O,P| = k$ so that $P \in \mathcal{C}(O;k)$. By 2.1.3 any point $X \neq P$ of the half-line $[O,P$ must satisfy either $X \in [O,P]$ or $P \in [O,X]$. If $X \in [O,P]$ then by 3.1.2 $|O,X| < |O,P| = k$, so that $X$ is interior to the circle. On the other hand if $P \in [O,X]$ then $|O,X| > |O,P| = k$, and so $X$ is an exterior point for the circle. Moreover $Q$ is also on the circle and similar results hold when $X \in [O,Q$.

When $M \neq O$, we have $MP = l$, $MO = m$, so that $MP \perp MO$ and then by Pythagoras’ theorem

$$|O,P|^2 = |O,M|^2 + |M,P|^2 = |O,M|^2 + [k^2 - |O,M|^2] = k^2;$$

thus again $|O,P| = k$, so that $P$ is on the circle. By 2.1.3 any point $X \neq P$ of the half-line $[M,P$ must satisfy either $X \in [M,P]$ or $P \in [M,X]$. If $X \in [M,P]$, then by 3.1.2 $|M,X| < |M,P|$; when $X = M$, clearly $X$ an interior point; when $X \neq M$, by Pythagoras’ theorem this gives

$$|O,X|^2 = |O,M|^2 + |M,X|^2 < |O,M|^2 + |M,P|^2 = k^2,$$

so that $|O,X| < k$ and so again $X$ is interior to the circle. If on the other hand $P \in [M,X]$, while still $X \neq P$, then by 3.1.2 $|M,X| > |M,P|$; by Pythagoras’ theorem we have

$$|O,X|^2 = |O,M|^2 + |M,X|^2 > |O,M|^2 + |M,P|^2 = k^2,$$

so that $|O,X| > k$ and so $X$ is exterior to the circle. Thus the points of $[M,P] \setminus \{P\}$ are interior to the circle, and the points of $([M,P) \setminus [M,P]$ are exterior to the circle.
Similar results hold when \( X \in [M, Q] \), that is the points of \([M, Q] \setminus \{Q\}\) are interior to the circle while the points of \((M, Q) \setminus [M, Q]\) are exterior to the circle. But \( M \in [P, Q] \) so that \([P, M] \cup [M, Q] = [P, Q]\), \([M, P] \cup [M, Q] = PQ\) and so we can take these results together. Thus the points of \([P, Q]\), other than \( P \) and \( Q \), are interior to the circle, and the points of \( PQ \setminus [P, Q]\) are exterior to the circle, leaving just the points \( P \) and \( Q \) of the line \( l = PQ \) in the circle.

(iii) Suppose that \( |O, M| > k \), so that \( M \) is exterior to the circle. Then \( M \in l \) and \( OM \perp l \). If \( X \in l, X \neq M \), then by 4.3.1, \( |O, X| > |O, M| > k \), so that \( X \) is exterior to the circle.

**Definition.** If \( l \) is a line such that \( l \cap C(O; k) = \{P\} \) for a point \( P \), then \( l \) is called a tangent to \( C(O; k) \) at \( P \), and \( P \) is called the point of contact. If \( l \cap C(O; k) = \{P, Q\} \) for distinct points \( P \) and \( Q \), then \( l \) is called a secant for \( C(O; k) \) and the segment \([P, Q]\) is called a chord of the circle; when \( O \in l = PQ \), the chord \([P, Q]\) is called a diameter of the circle; in that case \( O = mp(P, Q) \). If \( l \cap C(O; k) = \emptyset \), then \( l \) is called a non-secant line for the circle.

**NOTE.** By the above every point of a tangent to a circle, other than the point of contact, is an exterior point. If \([P, Q]\) is a chord, every point of the chord other than its end-points \( P \) and \( Q \) is an interior point, while every point of \( PQ \setminus [P, Q]\) is exterior. Every point of a non-secant line is an exterior point.

### 7.2 PROPERTIES OF CIRCLES

#### 7.2.1

Circles have the following properties:

(i) If \([Q, S]\) is a diameter of the circle \( C(O; k) \) and \( P \) any point of the circle other than \( Q \) and \( S \), then \( PQ \perp PS \).

(ii) If points \( P, Q, S \) are such that \( PQ \perp PS \), then \( P \) is on a circle with diameter \([Q, S]\).

(iii) If \( P \) is any point of the circle \( C(O; k) \), \([Q, S]\) is any diameter and \( U = \pi_{QS}(P) \), then \( U \in [Q, S] \) and \( |Q, U| \leq 2k \).

(iv) If \( Q \) is a point of a circle with centre \( O \) and \( l \) is the tangent to the circle at \( Q \), then every point of the circle lies in the closed half-plane with edge \( l \) in which \( O \) lies.
Circles; their basic properties

7.2

Figure 7.2.

Proof.

(i) By 5.2.2

\[ |\angle OSP| + |\angle SPO| + |\angle POS| = 180, \quad |\angle OQP| + |\angle QPO| + |\angle POQ| = 180. \]

But by 4.1.1,

\[ |\angle OSP| = |\angle SPO|, \quad |\angle OQP| = |\angle QPO|, \]

and so

\[ 2|\angle SPO| + 2|\angle QPO| + |\angle POS| + |\angle POQ| = 360. \]

Now \( O \in [Q, S] \) so \( |\angle POS| + |\angle POQ| = 180 \), and as \( [P, O] \subset H([QPS]) \) we have \( |\angle SPO| + |\angle OPQ| = |\angle QPS| \). Thus \( |\angle QPS| = 90 \).

(ii) Let \( O \) be the mid-point of \( Q \) and \( S \) and through \( O \) draw the line parallel to \( PQ \). It will meet \([P, S]\) in a point \( M \). Then by 5.3.1 \( M \) is the mid-point of \( P \) and \( S \). But \( PQ \perp PS \) and \( PQ \parallel MO \) so by 5.1.1 \( MO \perp PS \). Then \( [O, P, M] \equiv [O, S, M] \) by the SAS principle of congruence. It follows that \( |O, P| = |O, S| \).

(iii) If \( P \notin QR \), then by (i) of the present theorem and 4.3.3 \( U \in [Q, S] \). If \( P \in QS \) then \( U \) is either \( Q \) or \( S \) and so \( U \in [Q, S] \). Then by 3.1.2 \( |Q, U| \leq |Q, S| \). But as \( O = mp(Q, S) \), by 3.2.1 \( |Q, O| = \frac{1}{2} |Q, S| \), and so \( |Q, S| = 2k \).

(iv) Let \([Q, S]\) be the diameter containing \( Q \) and \( H \) the closed half-plane with edge \( l \) which contains \( O \). Then by 2.2.3 every point of \([Q, O]\) lies in \( H \). If \( P \) is any point of the circle and \( U = \pi_{QO}(P) \) then by (iii) above \( U \in [Q, S] \subset [Q, O] \), so \( U \in H \). But \( l \perp QS \), \( UP \perp QS \) so \( UP \parallel l \). Then by 4.3.2 \( P \in H \).

7.2.2 Equation of a circle

Let \( Z_0 = (x_0, y_0) \) and \( k > 0 \). Then \( Z \equiv (x, y) \) is on \( C(Z_0; k) \) if and only if

\[ (x - x_0)^2 + (y - y_0)^2 = k^2. \]

Proof. This is immediate by the distance formula in 6.1.1.

7.2.3 Circle through three points

Given any three non-collinear points \( A, B \) and \( C \), there is a unique circle which passes through them.
**Proof.** Let \( l \) and \( m \) be the perpendicular bisectors of \([B,C]\) and \([C,A]\), respectively. Then if we had \( l \parallel m \) we would have \( l \parallel m \), \( m \perp CA \) and so \( l \perp CA \) by 5.1.1; this would yield \( BC \perp l \), \( CA \perp l \) and so \( BC \parallel CA \) by 4.2.2(iv). This would make the points \( A, B, C \) collinear and so give a contradiction.

Thus \( l \) must meet \( m \) in a unique point, \( D \) say. Then by 4.1.1(iii) \( D \) is equidistant from \( B \) and \( C \) as it is on \( l \), and it is equidistant from \( C \) and \( A \) as it is on \( m \). Thus the circle with centre \( D \) and length of radius \(|D,A|\) passes through \( A, B \) and \( C \).

Conversely, suppose that a circle passes through \( A, B \) and \( C \). Then by 4.1.1(ii) its centre must be on \( l \) and on \( m \) and so must be \( D \). The length of radius then must be \(|D,A|\).

**Corollary.** Two distinct circles cannot have more than two points in common.

### 7.3 Formula for Mid-line of an Angle-support

**Comment.** We now start to prepare the ground for our treatment of angles. Earlier on we found that mid-points have a considerable role. Now we shall find that mid-lines of angle-supports, dealt with in 3.6, have a prominent role as well. Given any angle-support \( \angle BAC \), if we take any number \( k > 0 \) there are unique points \( P_1 \) and \( P_2 \) on \([A,B] \) and \([A,C] \) respectively, such that \(|A,P_1| = k\), \(|A,P_2| = k\). Thus \( P_1 \) and \( P_2 \) are the points of \([A,B] \) and \([A,C] \) on the circle \( C(A;k) \). Then \( \angle BAC = \angle P_1AP_2 \) and it is far more convenient to work with the latter form. We first prove a result which will enable us to deal with the mid-lines of angle-supports by means of Cartesian coordinates.

With a frame of reference \( \mathcal{F} = ([O,I], [O,J]) \), let \( P_1, P_2 \in C(O;1) \) be such that \( P_1 \equiv \mathcal{F}(a_1,b_1), P_2 \equiv \mathcal{F}(a_2,b_2) \). Then the mid-line \( l \) of \( P_1OP_2 \) has equation

\[
(b_1 + b_2)x - (a_1 + a_2)y = 0
\]

when \( P_1 \) and \( P_2 \) are not diametrically opposite, and equation \( a_1x + b_1y = 0 \) when they are.

**Proof.** When \( P_1 \) and \( P_2 \) are not diametrically opposite, their mid-point \( M \) is not \( O \) and we have \( l = OM \). As \( M \) has coordinates \( \left( \frac{1}{2}(a_1 + a_2), \frac{1}{2}(b_1 + b_2) \right) \), the line \( OM \) has equation \((b_1 + b_2)x - (a_1 + a_2)y = 0\). When \( P_1 \) is diametrically opposite to \( P_2 \), \( l \) is the line through \( O \) which is perpendicular to \( OP \) and this has the given equation.

![Figure 7.3](image-url)
With the notation of the last result, let $Q \equiv (1,0)$ and $s_l(Q) = P_3$ where $P_3 \equiv (a_3, b_3)$. Then
\[
a_3 = \frac{(a_1 + a_2)^2 - (b_1 + b_2)^2}{(a_1 + a_2)^2 + (b_1 + b_2)^2}, \quad b_3 = \frac{2(a_1 + a_2)(b_1 + b_2)}{(a_1 + a_2)^2 + (b_1 + b_2)^2},
\]
when $P_1$ and $P_2$ are not diametrically opposite, and
\[
a_3 = b_1^2 - a_1^2, \quad b_3 = -2a_1b_1,
\]
when they are.

**Proof.** For $l \equiv ax + by + c = 0$, we recall from 6.6.1 that
\[
s_l(Z_0)
\equiv \left( x_0 - \frac{2a}{a^2 + b^2}(ax_0 + by_0 + c), y_0 - \frac{2b}{a^2 + b^2}(ax_0 + by_0 + c) \right).
\]
When $P_1$ and $P_2$ are not diametrically opposite, $l \equiv (b_1 + b_2)x - (a_1 + a_2)y = 0$. Thus for it $x_0 = 1, y_0 = 0, a = b_1 + b_2, b = -(a_1 + a_2), c = 0$ and so
\[
a_3 = \frac{(a_1 + a_2)^2 - (b_1 + b_2)^2}{(a_1 + a_2)^2 + (b_1 + b_2)^2}, \quad b_3 = \frac{2(a_1 + a_2)(b_1 + b_2)}{(a_1 + a_2)^2 + (b_1 + b_2)^2}.
\]

When $P_1$ and $P_2$ are diametrically opposite, $l \equiv a_1x + b_1y = 0$. Thus for it $x_0 = 1, y_0 = 0, a = a_1, b = b_1, c = 0$, so we have
\[
a_3 = b_1^2 - a_1^2, \quad b_3 = -2a_1b_1,
\]
as $a_1^2 + b_1^2 = 1$.

### 7.4 POLAR PROPERTIES OF A CIRCLE

#### 7.4.1 Tangents from an exterior point

Let $P$ be a point exterior to a circle $\mathcal{C}$. Then two tangents to the circle pass through $P$. Their points of contact are equidistant from $P$.

**Proof.** Let the circle have centre $O$ and length of radius $a$. Let $|O, P| = b$, so that $b > a$. Choose the point $U \in [O, P]$ so that $x = |O, U| = a^2/b$. As $b > a$, then $x < a < b$ so $U \in [O, P]$. Erect a perpendicular to $OP$ at $U$ and mark off on it a distance
\[
y = |U, T_1| = a \sqrt{1 - \left(\frac{a}{b}\right)^2}.
\]
By Pythagoras’ theorem,
\[ |O, T_1|^2 = |O, U|^2 + |U, T_1|^2 = x^2 + y^2 = \frac{a^4}{b^2} + a^2 - \frac{a^4}{b^2} = a^2, \]
so that \( T_1 \in \mathcal{C} \).

Let \( V \) be the mid-point of \( O \) and \( P \), so that \( V \in [O, P] \) and \( |O, V| = \frac{b}{2} \). Then
\[ |U, V| = \pm (|O, V| - |O, U|) = \pm (\frac{1}{2}b - x). \]

Again by Pythagoras’ theorem,
\[ |V, T_1|^2 = |U, V|^2 + |U, T_1|^2 = (\frac{1}{2}b - x)^2 + y^2 = \left( \frac{1}{2}b - \frac{a^2}{b} \right)^2 + a^2 \left( 1 - \frac{a^2}{b^2} \right) = \frac{1}{4}b^2. \]

Thus \( T_1 \) is on the circle \( \mathcal{C}_1 \) with centre \( V \) and radius length \( \frac{1}{2}b \). Note that \( \mathcal{C}_1 \) also passes through \( O \) and \( P \). Then \( \angle OT_1P \) is an angle in a semi-circle of \( \mathcal{C}_1 \), so that by 7.2.1 it is a right-angle. Thus by 7.1.1 \( PT_1 \) is a tangent to \( \mathcal{C} \) at \( T_1 \).

By a similar argument, if we take \( T_2 \) so that \( U \) is the mid-point of \( T_1 \) and \( T_2 \), then \( PT_2 \) is also a tangent to \( \mathcal{C} \) at \( T_2 \). We note that \( T_1 \) and \( T_2 \) are both on the line which is perpendicular to \( OP \) at the point \( U \).

By Pythagoras’ theorem
\[ |P, T_1|^2 = |O, P|^2 - |O, T_1|^2 = |O, P|^2 - |O, T_2|^2 = |P, T_2|^2, \]
and so \( |P, T_1| = |P, T_2| \).

There cannot be a third tangent \( PT_3 \) as then \( T_3 \) would be on \( \mathcal{C} \) and \( \mathcal{C}_1 \), whereas by 7.2.3 these circles have only two points in common.

### 7.4.2 The power property of a circle

For a fixed circle \( \mathcal{C}(O; k) \) and fixed point \( P \notin \mathcal{C}(O; k) \), let a variable line \( l \) through \( P \) meet \( \mathcal{C}(O; k) \) at \( R \) and \( S \). Then the product of distances \( |P, R||P, S| \) is constant. When \( P \) is exterior to the circle,
\[ |P, R||P, S| = |P, T_1|^2, \]
where \( T_1 \) is the point of contact of a tangent from \( P \) to the circle.

**Proof.** By the distance formula \( Z \equiv (x, y) \) is on \( \mathcal{C}(O; k) \) if and only if \( x^2 + y^2 - k^2 = 0 \). If \( P \equiv (x_0, y_0) \) and \( l \) has Cartesian equation \( ax + by + c = 0 \), by 6.4.1 points \( Z \) on \( l \) have parametric equations of the form \( x = x_0 + bt \), \( y = y_0 - at \) \((t \in \mathbb{R})\). Now \( l \) also has Cartesian equation
\[ \frac{a}{\sqrt{a^2 + b^2}}x + \frac{b}{\sqrt{a^2 + b^2}}y + \frac{c}{\sqrt{a^2 + b^2}} = 0. \]
Thus as we we may replace \( a \) and \( b \) by \( a/\sqrt{a^2+b^2} \) and \( b/\sqrt{a^2+b^2} \), without loss of generality we may assume that \( a^2 + b^2 = 1 \). Then the point \( Z \) on the line lies on the circle if \((x_0 + bt)^2 + (y_0 - at)^2 - k^2 = 0\), that is if

\[
t^2 + 2(bx_0 - ay_0)t + x_0^2 + y_0^2 - k^2 = 0.
\]

If \( t_1, t_2 \) are the roots of this equation, then \( t_1 t_2 = x_0^2 + y_0^2 - k^2 \). A sf or \( R \) and \( S \) we have \( x_1 = x_0 + bt_1, \ y_1 = y_0 - at_1, \ x_2 = x_0 + bt_2, \ y_2 = y_0 - at_2; \) so \( |P, R| = |t_1|, \ |P, S| = |t_2| \). Thus

\[
|P, R||P, S| = |t_1 t_2| = |x_0^2 + y_0^2 - k^2|,
\]

which is constant.

When \( P \) is exterior to the circle, the roots of the quadratic equation are equal if

\[
(bx_0 - ay_0)^2 = x_0^2 + y_0^2 - k^2,
\]

and the repeated root is given by \( t = -(bx_0 - ay_0) \). Then for a point of intersection \( T_1 \) of the line and circle, we have for the coordinates of \( T_1 \)

\[
x = x_0 - (bx_0 - ay_0)b, \quad y = y_0 + (bx_0 - ay_0)a.
\]

Hence

\[
|P, T_1|^2 = (x - x_0)^2 + (y - y_0)^2 = (bx_0 - ay_0)^2 = x_0^2 + y_0^2 - k^2 = |O, P|^2 - k^2.
\]

It is also easy to give a synthetic proof as follows. We first take \( P \) interior to the circle. Let \( M \) be the mid-point of \( R \) and \( S \) so that \( M \) is the foot of the perpendicular from \( O \) to \( RS \). Then \( P \) is in either \([R, M]\) or \([M, S]\); we suppose that \( P \in [R, M] \).

Then

\[
\]

\[
= |M, R|^2 - (|P, O|^2 - |O, M|^2) = (|M, R|^2 + |O, M|^2) - |P, O|^2
\]

\[
= |O, R|^2 - |P, O|^2 = k^2 - |P, O|^2,
\]

Figure 7.5.
and this is fixed.

We continue with the case where $P$ is exterior to the circle, and may suppose that $|PR| < |PS|$, as otherwise we can just interchange the points $R$ and $S$. As $P$ is outside the circle, by 7.1.1 it is outside the segment $[R, S]$ on the line $RS$. Then we have

$$|PR||PS| = (|PM| - |MR|)(|PM| + |MS|) = |PM|^2 - |MR|^2$$

$$= (|PO|^2 - |OM|^2) - |MR|^2 = |PO|^2 - (|OM|^2 + |MR|^2)$$

$$= |PO|^2 - |OR|^2 = |PO|^2 - |OT|_1|^2 = |P, T_1|^2.$$ 

### 7.4.3 A harmonic range

Let $T_1$ and $T_2$ be the points of contact of the tangents from an exterior point $P$ to a circle $\mathcal{C}$ with centre $O$. If a line $l$ through $P$ cuts $\mathcal{C}$ in the points $R$ and $S$, and cuts $T_1T_2$ in $Q$, then $P$ and $Q$ divide $[R, S]$ internally and externally in the same ratio.

**Proof.** We use the notation of 7.4.1 and first recall that $T_1T_2$ cuts $OP$ at right-angles at a point $U$. Then, by 7.2.1(ii), the circle $\mathcal{C}_2$ on $[O, Q]$ as a diameter passes through $U$. We let $M$ be the midpoint of $R$ and $S$; then by 4.1.1 $OM \perp MQ$, and so $M$ also lies on the circle $\mathcal{C}_2$.

![Figure 7.6](image)

We have $|PR||PS| = |P, T_1|^2$ by 7.4.2, $|P, T_1|^2 = |P, U||P, O|$ by the proof of Pythagoras’ theorem in 5.4.1, and $|P, U||P, O| = |P, Q||P, M|$, by the 7.4.2 applied to the circle $\mathcal{C}_2$. On combining these we have $|PR||PS| = |P, Q||P, M|$.

We cannot have $l \perp OP$ as that would make $l \parallel T_1T_2$ whereas $l$ meets $T_1T_2$. Then, with the notation of 7.4.1, $l$ is not a tangent to $\mathcal{C}_1$ at $P$ so, by 7.1.1 $l$ must meet $\mathcal{C}_1$ at a point $H$. We are supposing that $l$ is not either of $PT_1$, $PT_2$ and so $H$ is not $T_1$ or $T_2$. We let $K$ be the foot of the perpendicular from $H$ to $OP$. Then by 4.3.3 $K \in [P, O]$ and by the proof of Pythagoras’ theorem in 5.4.1 $|P, H|^2 = |P, K||P, O|$. If we had $K \in [P, U]$ we would have $|P, K| < |P, U|$ and so

From this it would follow that

$$|O, H|^2 = |O, P|^2 - |P, H|^2 > |O, P|^2 - |P, T_1|^2 = a^2,$$

and make $H$ exterior to the circle. But $H$ is the foot of the perpendicular from $O$ to $l$, and by 7.1.1 this would cause $l$ to have no point in common with the circle. This cannot occur and so we must have $K \in [O, U]$. By a similar argument it then follows that $H$ is interior to the circle $\mathcal{C}$ and so $l$ meets $\mathcal{C}$ in two points $R$ and $S$.

By 7.2.1(iv) every point of the circle $\mathcal{C}$ is in the closed half-plane $\mathcal{H}_1$ with edge $PT_1$ and which contains $O$. By 2.2.3 $\mathcal{H}_1$ contains $U \in [P, O$ and then it also contains
$T_2 \in [T_1, U]$. Similarly every point of $C$ is also in the closed half-plane with edge $PT_2$ and which contains $T_1$. It follows that every point of $C$ lies in the interior region $\mathcal{R}(T_1PT_2)$. Now every point of $[P, R]$ is in this interior region and so $Q$ is. It follows that $Q \in [T_1, T_2]$ and so by 7.1.1 is interior to the circle; we thus must have $Q \in [R, S]$ by 7.1.1 again.

We let $x = |P, R|$, $y = |P, S|$, $z = |P, Q|$, and without loss of generality assume $|P, R| < |P, S|$ so that $x < y$. As $P$ is outside the circle it is outside the segment $[R, S]$; as $Q$ is on the segment $[R, S]$, it follows that $0 < x < z < y$. Then in turn

$$xy = \frac{1}{2}(x+y)z,$$

$$z-x = x = \frac{1}{2} + \frac{1}{y},$$

$$z-x = y - y = \frac{1}{z} - \frac{1}{y}.$$

In the above we have assumed that $l$ is not the line $OP$. When it is we have a simple case; $l$ cuts the circle in points $R_1, S_1$ such that $[R_1, S_1]$ is a diameter. Then taking $|P, R_1| < |P, S_1|$, with the notation of 7.4.1 we have that

$$\frac{|S_1, P|}{|P, R_1|} = \frac{b + a}{b - a}, \quad \frac{|S_1, U|}{|U, R_1|} = \frac{a + a^2/b}{a - a^2/b},$$

and these are equal.

### 7.5 ANGLES STANDING ON ARCS OF CIRCLES

#### 7.5.1

Let $P, Q, R, S$ be points of a circle $C(O; k)$ such that $R$ and $S$ are on one side of the line $PQ$. Then $|\angle PRQ| = |\angle PSQ|$.

(i) When $O \in PQ$, $|\angle PRQ| = 90$.

(ii) When $O \notin PQ$ and $R$ is on the same side of $PQ$ as $O$ is, then $|\angle PRQ| = \frac{1}{2} |\angle POQ|$.

(iii) When $O \notin PQ$ and $R$ is on the opposite side of $PQ$ from $O$, then $|\angle PRQ|$ is equal to half of the degree-measure of the reflex-angle with support $|PQ|$.

**Proof.** We are given that $R \notin PQ, S \notin PQ$. Now $S \notin QR$ as by 7.1.1 a line cannot meet the circle in more than two points; for this reason also $S \notin RP$. Thus $S$ cannot be on a side-line of the triangle $[P, Q, R]$. Moreover, neither can $S$ be in $[P, Q, R]$ but not on a side, as then by the cross-bar theorem we would have $S \in [P, V]$ for some point $V$ in $[Q, R]$ but not at an end-point. Then $V$ would be interior to the circle and $P$ is on the circle, so by 7.1.1 every point of $[P, V]$, other than $P$, is interior to the circle; this would make $S$ interior to the circle whereas it is on it.

Thus as $S \notin [P, Q, R]$ we must have at least one of the following :-

(a) $S$ is on the opposite side of $QR$ from $P$,
(b) $S$ is on the opposite side of $RP$ from $Q$,
(c) $S$ is on the opposite side of $PQ$ from $R$,
and of course (c) is ruled out by assumption.

We suppose that (a) holds as in the first figure; the case of (b) is treated similarly. Then there is a point \( U \in [P,S] \cap QR \). As \( U \in [P,S] \), \( U \) must be an interior point for the circle and hence we must have \( U \in [Q,R] \). By 7.4.2

\[
\frac{|U,P|}{|U,Q|} = \frac{|U,R|}{|U,S|},
\]

and we also have \( \angle PUR^\circ = \angle QUS^\circ \) as these are opposite angles. By 5.3.2, the triangles \([U,P,R],[U,Q,S]\) are similar. In particular \( \angle PRU^\circ = \angle QSU^\circ \). The first diagram in Fig. 7.7 deals with this general case.

In (i) when \( O \in PQ \), that we have a right-angle comes from 7.2.1 and there is a diagram for this in Fig. 7.2.

When \( O \notin PQ \) we let \( V \) be the mid-point of \([P,Q]\) and for the second case (ii), as in the second diagram in Fig. 7.7, we take \( R \) to be point in which \( [V,O] \) meets the circle. Then by 5.2.2, Corollary, and 4.1.1(i) \( \angle VOP^\circ = 2\angle VRP^\circ \), \( \angle VOQ^\circ = 2\angle VRQ^\circ \).

But \([R,V] \subset IR([PRQ]) \) so that \( \angle VOP^\circ \) + \( \angle VRQ^\circ = \angle PRQ^\circ \). Moreover \([O,V] \subset IR([POQ]) \) so that \( \angle VOP^\circ + \angle VOQ^\circ = \angle POQ^\circ \). By addition we then have that \( \angle POQ^\circ = 2\angle PRQ^\circ \).

For the third case (iii), as in the third diagram in Fig. 7.7, we take \( R \) to be point in which \( [O,V] \) meets the circle and \( W \neq O \) a point such that \( O \in [V,W] \). Then by 5.2.2, Corollary, and 4.1.1(i) \( \angle WOP^\circ = 2\angle WRP^\circ \), \( \angle WOQ^\circ = 2\angle WRQ^\circ \).

But \([R,W] \subset IR([PRQ]) \) so that \( \angle WRP^\circ + \angle WRQ^\circ = \angle PRQ^\circ \). Moreover \([O,V] \subset IR([POQ]) \) so that by 3.7.1 \( \angle WOP^\circ + \angle WOQ^\circ \) is equal to the degree-measure...
of the reflex-angle with support $|\angle POQ|$. By addition we then have that the degree-measure of this reflex-angle is equal to $2|\angle PRQ|°$.

**Definition.** If the vertices of a convex quadrilateral all lie on some circle, then the quadrilateral is said to be **cyclic**.

**COROLLARY.** Let $[P, Q, R, S]$ be a convex cyclic quadrilateral. Then the sum of the degree-measures of a pair of opposite angles is 180.

**Proof.** Using the fourth diagram in Fig. 7.7, we first note that $|\angle RPQ|° + |\angle PQR|° = 180$. Next as $[S, Q] \subset \mathcal{H}(\mathbb{P}SR)$, we have $|\angle PSR|° = |\angle PSQ|° + |\angle QSR|°$. But $|\angle PSQ|° = |\angle QRP|°$, $|\angle QSR|° = |\angle RPQ|°$. Hence $|\angle PSR|° + |\angle PQR|° = |\angle RPQ|° + |\angle PQR|° + |\angle QRP|° = 180$.

### 7.5.2 Minor and major arcs of a circle

**Definition.** Let $P_1, P_2 \in \mathcal{C}(O;k)$ be distinct points such that $O \notin P_1P_2$. Let $\mathcal{H}_5, \mathcal{H}_6$ be the closed half-planes with edge $P_1P_2$, with $O \in \mathcal{H}_5$. Then $\mathcal{C}(O;k) \cap \mathcal{H}_5$, $\mathcal{C}(O;k) \cap \mathcal{H}_6$, are called, respectively, the **major** and **minor arcs** of $\mathcal{C}(O;k)$ with **end-points** $P_1$ and $P_2$.

The point $P \in \mathcal{C}(O;k)$ is in the minor arc with end-points $P_1, P_2$ if and only if $[O, P] \cap [P_1, P_2] \neq \emptyset$.

**Proof.** Let $P$ be in the minor arc. Then $O \in \mathcal{H}_5, P \in \mathcal{H}_6$ so $[O, P]$ meets $P_1P_2$ in some point $W$. As $W \in [O, P]$ we have $|O, W| \leq k$ so by 7.1.1 $W \in [P_1, P_2]$.

Conversely suppose that $W \in [P_1, P_2]$ so that $|O, W| \leq k$. Choose $P \in [O, W]$ so that $|O, P| = k$. Then as $|O, W| \leq |O, P|$ we have $W \in [O, P]$ so that as $O \in \mathcal{H}_5$ we have $P \in \mathcal{H}_6$.

### 7.6 SENSED DISTANCES

#### 7.6.1 Sensed distance

**Definition.** If $l$ is a line, $\leq_l$ is a natural order on $l$ and $Z_1, Z_2 \in l$, then we define $Z_1Z_2\leq_l$ by

$$
\overline{Z_1Z_2}_{\leq_l} = \begin{cases} 
|Z_1, Z_2|, & \text{if } Z_1 \leq_l Z_2, \\
-|Z_1, Z_2|, & \text{if } Z_2 \leq_l Z_1,
\end{cases}
$$

and call this the **sensed distance** from $Z_1$ to $Z_2$. In knowing this rather than just the distance from $Z_1$ to $Z_2$ we have extra information which can be turned to good
account. It can have negative as well as positive and zero values and it is related to the distance as $Z_1 Z_2 \leq l = \pm |Z_1, Z_2|$ or equivalently $|Z_1 Z_2 \leq l| = |Z_1, Z_2|$.

We note immediately the properties:

$$Z_1 Z_1 \leq l = 0, \quad (7.6.1)$$
$$Z_2 Z_1 \leq l = -Z_1 Z_2 \leq l, \quad (7.6.2)$$

in all cases. We can add sensed distances on a line and have the striking property that

$$Z_1 Z_2 \leq l + Z_2 Z_3 \leq l = Z_1 Z_3 \leq l, \quad (7.6.3)$$

for all $Z_1$, $Z_2$, $Z_3 \in l$.

This is easily seen to hold by (7.6.1) when any two of the three points coincide, as e.g. when $Z_1 = Z_2$ it amounts to $0 + Z_1 Z_3 \leq l = Z_1 Z_3 \leq l$. Suppose then that $Z_1$, $Z_2$, $Z_3$ are all distinct and suppose first that $Z_1 \leq l Z_2$. Then by 2.1.3 we have one of the cases

(a) $Z_3 \leq l Z_1 \leq l Z_2$, \quad (b) $Z_1 \leq l Z_3 \leq l Z_2$, \quad (c) $Z_1 \leq l Z_2 \leq l Z_3$.

In (a) we have

$$Z_1 Z_2 \leq l = |Z_1, Z_2|, \quad Z_2 Z_3 \leq l = -|Z_2, Z_3|, \quad Z_1 Z_3 \leq l = -|Z_1, Z_3|,$$

and as $Z_1 \in [Z_3, Z_2]$, $|Z_3, Z_1| + |Z_1, Z_2| = |Z_3, Z_2|$, which is

$$-Z_1 Z_3 \leq l + Z_1 Z_2 \leq l = -Z_2 Z_3 \leq l.$$

In (b) we have

$$Z_1 Z_2 \leq l = |Z_1, Z_2|, \quad Z_2 Z_3 \leq l = -|Z_2, Z_3|, \quad Z_1 Z_3 \leq l = Z_1, Z_3|,$$

and as $Z_3 \in [Z_1, Z_2]$, $|Z_1, Z_3| + |Z_3, Z_2| = |Z_1, Z_2|$, which is $Z_1 Z_3 \leq l - Z_2 Z_3 \leq l = Z_1 Z_2 \leq l$.

In (c) we have

$$Z_1 Z_2 \leq l = |Z_1, Z_2|, \quad Z_2 Z_3 \leq l = |Z_2, Z_3|, \quad Z_1 Z_3 \leq l = Z_1, Z_3|,$$

and as $Z_2 \in [Z_1, Z_3]$, $|Z_1, Z_2| + |Z_2, Z_3| = |Z_1, Z_3|$, which is $Z_1 Z_2 \leq l + Z_2 Z_3 \leq l = Z_1 Z_3 \leq l$.

Next suppose that $Z_2 \leq l Z_1$. Then on interchanging $Z_1$ and $Z_2$ in the cases just proved we have $Z_2 Z_1 \leq l + Z_1 Z_3 \leq l = Z_2 Z_3 \leq l$, for all $Z_3 \in l$ and by (7.6.2) this gives

$$-Z_1 Z_2 \leq l + Z_1 Z_3 \leq l = -Z_2 Z_3 \leq l.$$

This completes the proof of (7.6.3) which shows that addition of sensed distances on a line is much simpler than addition of distances.

We next relate sensed distances to the parametric equations of $l$ noted in 6.4.1. Corollary. Suppose that $W_0 \equiv (u_0, v_0)$, $W_1 \equiv (u_1, v_1)$ are distinct points on $l$ and that $W_0 \leq l W_1$. Then for points $Z_1 \equiv (x_1, y_1)$, $Z_2 \equiv (x_2, y_2)$ on $l$ we have

$$x_1 = u_0 + s_1 (u_1 - u_0), \quad y_1 = v_0 + s_1 (v_1 - v_0),$$
$$x_2 = u_0 + s_2 (u_1 - u_0), \quad y_2 = v_0 + s_2 (v_1 - v_0),$$

and we recall that $Z_1 \leq l Z_2$ if and only if $s_1 \leq s_2$. Moreover, by the distance formula

$$|Z_1, Z_2| = |s_2 - s_1| |W_0, W_1|.$$
From these we conclude that

\[ Z_1Z_2 \leq t = (s_2 - s_1)|W_0, W_1|. \]  
(7.6.4)

In particular the simplest case of parametric representation in relation to sensed distances is when we additionally take \(|W_0, W_1| = 1\) as we then have \(Z_1Z_2 \leq t = s_2 - s_1\).

When we consider the reciprocal natural order on \(l\) we note that

\[ Z_1Z_2 \geq t = -Z_1Z_2 \leq t, \]

so that changing to the reciprocal natural order multiplies the value by \(-1\). As well as adding sensed distances on one line we can multiply or divide them. Now for \(Z_1, Z_2, Z_3, Z_4\) in \(l\),

\[ Z_3Z_4 \geq t, Z_1Z_2 \leq t = Z_3Z_4 \leq t, Z_1Z_2 \leq t, \]

so this \textbf{sensed product} is independent of which natural order is taken. Similarly, when \(Z_1 \neq Z_2\), we can take a ratio of sensed distances

\[ \frac{Z_3Z_4 \leq t}{Z_1Z_2 \leq t} = \frac{-Z_3Z_4 \leq t}{-Z_1Z_2 \leq t} = Z_3Z_4 \leq t, Z_1Z_2 \leq t, \]

and see that this \textbf{sensed ratio} is independent of whichever of \(\leq t, \geq t\) is used. When the line \(l\) is understood, we can relax our notation to \(Z_3Z_4 Z_1Z_2\) and \(Z_3Z_4 Z_1Z_2\) for these products and ratios.

If for \(Z_1, Z_2, Z \in l\) we take the parametric equations

\[ x = x_1 + t(x_2 - x_1), \quad y = y_1 + t(y_2 - y_1), \quad (t \in \mathbb{R}), \]

then we have that

\[ x = u_0 + [s_1 + t(s_2 - s_1)](u_1 - u_0), \quad y = v_0 + [s_1 + t(s_2 - s_1)](v_1 - v_0), \]

and by (7.6.4) we have that

\[ Z_1Z \leq t = t(s_2 - s_1)|W_0, W_1|, \quad Z_2 \leq t = (1 - t)(s_2 - s_1)|W_0, W_1|, \]

and so

\[ \frac{Z_1Z}{Z_2} = \frac{t}{1 - t}. \]  
(7.6.5)

Our main utilisation of these concepts is through sensed ratios; for example \((Z_1, Z_2, Z_3, Z_4)\) is a harmonic range when \(Z_1Z_3/Z_3Z_2 = -Z_1Z_4/Z_4Z_2\). It is convenient to defer the details until Chapter 11. However we make one use of sensed products in the next subsection.
7.6.2 Sensed products and a circle

The conclusion of 7.4.2 can be strengthened to replace $|P, R||P, S|$ by $PRPS$. In fact the initial analytic proof gives this but it also easily follows from the stated result as $PRPS = -|P, R||P, S|$ when $P$ is interior to the circle while $PRPS = |P, R||P, S|$ when $P$ is exterior to the circle. We now look to a converse type of result.

Suppose that $Z_1, Z_2$ and $Z_3$ are fixed non-collinear points. For a variable point $W$ let $Z_1W$ meet $Z_2Z_3$ at $W'$ and

$$WW'W'Z_1 = W'Z_2W'Z_3.$$  

Then $W$ lies on the circle which passes through $Z_1, Z_2$ and $Z_3$.

Proof. Without loss of generality we may take our frame of reference so that $Z_1 \equiv (0, y_1), Z_2 \equiv (x_2, 0), Z_3 \equiv (x_3, 0)$, and we take $W \equiv (u, v), W' \equiv (u', 0)$.

Then it is easily found that $u' = y_1 u/(y_1 - v)$, and so, first of all,

$$W'Z_2W'Z_3 = \left( x_2 - \frac{y_1 u}{y_1 - v} \right) \left( x_3 - \frac{y_1 u}{y_1 - v} \right).$$

The line $W'W$ has parametric equations $x = u' + s(u - u')$, $y = 0 + s(v - 0)$, with $s = 0$ giving $W'$ and $s = 1$ giving $W$. Thus $W'W = |W', W|$. The point $Z_1$ has parameter given by $y_1 = sv$ and so $s = y_1/v$; then $W'Z_1 = \frac{y_1}{v}|W', W|$. It follows that

$$W'W W'Z_1 = \frac{y_1}{v}|W', W|^2 = \frac{y_1}{v} \left[ \left( u - \frac{y_1 u}{y_1 - v} \right)^2 + v^2 \right] = y_1 v \left[ \left( \frac{u}{y_1 - v} \right)^2 + 1 \right].$$

On equating the two expressions we have

$$\left( x_2 - \frac{y_1 u}{y_1 - v} \right) \left( x_3 - \frac{y_1 u}{y_1 - v} \right) = y_1 v \left[ \left( \frac{u}{y_1 - v} \right)^2 + 1 \right],$$

which we re-write as

$$\frac{y_1 u^2 (y_1 - v)}{(y_1 - v)^2} = y_1 v - x_2 x_3 + \frac{y_1 (x_2 + x_3) u}{y_1 - v}.$$  

On multiplying across by $y_1 - v$ we obtain

$$y_1 (u^2 + v^2) - y_1 (x_2 + x_3) u - (y_1^2 + x_2 x_3) v + y_1 x_2 x_3 = 0,$$

and this is the equation of a circle.
7.6.3 Radical axis and coaxal circles

In 7.4.2 our proof showed that if a line through the point $Z$ meets the circle $\mathcal{C}(Z_1, k_1)$ at the points $R$ and $S$ then $\overline{ZRZS} = |Z_1, Z|^2 - k_1^2$ depends only on the circle and the point $Z$. We call this expression the power of the point $Z$ with respect to this circle. To cater for degenerate cases, when $k_1 = 0$ we also call $|Z_1, Z|^2$ the power of $Z$ with respect to the point $Z_1$.

We let $\mathcal{C}_1$ denote either $\mathcal{C}(Z_1, k_1)$ or $Z_1$ and similarly consider $\mathcal{C}_2$ which is either $\mathcal{C}(Z_2, k_2)$ or $Z_2$. We ask for what points $Z$ its powers with respect to $\mathcal{C}_1$ and $\mathcal{C}_2$ are equal. This occurs when $|Z_1, Z|^2 - k_1^2 = |Z_2, Z|^2 - k_2^2$ which simplifies to

$$2(x_2 - x_1)x + 2(y_2 - y_1)y + x_1^2 + y_1^2 - k_1^2 + x_2^2 + y_2^2 - k_2^2 = 0.$$ 

If $Z_1 \neq Z_2$ this is the equation of a line which is called the radical axis of $\mathcal{C}_1$ and $\mathcal{C}_2$. It is always perpendicular to the line $Z_1Z_2$ and it passes through any points which $\mathcal{C}_1$ and $\mathcal{C}_2$ have in common.

More generally we also ask for what points $Z$ its powers with respect to $\mathcal{C}_1$ and $\mathcal{C}_2$ have a constant ratio. For a real number $\lambda$ which is not equal to 1 we consider when

$$|Z_1, Z|^2 - k_1^2 = \lambda \left[ |Z_2, Z|^2 - k_2^2 \right]. \quad (7.6.6)$$

When $\lambda = 0$ this yields $\mathcal{C}_1$ and by considering $\mu \left[ |Z_1, Z|^2 - k_1^2 \right] = |Z_2, Z|^2 - k_2^2$ as well, we also include $\mathcal{C}_2$.

Now (7.6.6) expands to

$$x^2 + y^2 - 2 \frac{x_1 - \lambda x_2}{1 - \lambda} x - 2 \frac{y_1 - \lambda y_2}{1 - \lambda} y + \frac{x_1^2 + y_1^2 - k_1^2 - \lambda(x_2^2 + y_2^2 - k_2^2)}{1 - \lambda} = 0,$$

and on completing the squares in both $x$ and $y$ it becomes

$$\left( x - \frac{x_1 - \lambda x_2}{1 - \lambda} \right)^2 + \left( y - \frac{y_1 - \lambda y_2}{1 - \lambda} \right)^2 = \frac{1}{(1 - \lambda)^2} \left\{ k_1^2 + [(x_1 - x_2)^2 + (y_1 - y_2)^2 - k_1^2 - k_2^2] \lambda + k_2^2 \lambda^2 \right\}.$$

This quadratic expression in $\lambda$ is posite when $|\lambda|$ is large, so it has either a positive minimum, or its minimum is 0 attained at $\lambda_1$, say, or it has a negative minimum and so has the value 0 at $\lambda_2$ and $\lambda_3$, say, where $\lambda_2 < \lambda_3$. In the first of these cases (7.6.6) always represents a circle and in the second case it represents a circle for all $\lambda \neq \lambda_1$ and a point for $\lambda = \lambda_1$. In the third case it represents a circle when either $\lambda < \lambda_2$ or $\lambda > \lambda_3$, it represents a point when either $\lambda = \lambda_2$ or $\lambda = \lambda_3$, and it represents an empty locus when $\lambda_2 < \lambda < \lambda_3$. Thus it is the equation of a circle, a point or an empty locus.

Suppose that we consider two of these loci, corresponding to the values $\lambda_4$ and $\lambda_5$ of $\lambda$. They will then have equations

$$x^2 + y^2 - 2 \frac{x_1 - \lambda_4 x_2}{1 - \lambda_4} x - 2 \frac{y_1 - \lambda_4 y_2}{1 - \lambda_4} y + \frac{x_1^2 + y_1^2 - k_1^2 - \lambda_4(x_2^2 + y_2^2 - k_2^2)}{1 - \lambda_4} = 0,$$

$$x^2 + y^2 - 2 \frac{x_1 - \lambda_5 x_2}{1 - \lambda_5} x - 2 \frac{y_1 - \lambda_5 y_2}{1 - \lambda_5} y + \frac{x_1^2 + y_1^2 - k_1^2 - \lambda_5(x_2^2 + y_2^2 - k_2^2)}{1 - \lambda_5} = 0.$$
On subtracting the second of these from the first, and simplifying, we find that their radical axis is the line with equation

\[
\frac{\lambda_4 - \lambda_5}{(1 - \lambda_4)(1 - \lambda_5)} \left[ 2(x_2 - x_1)x + 2(y_2 - y_1)y + x_1^2 + y_1^2 - k_1^2 + x_2^2 + y_2^2 - k_2^2 \right] = 0.
\]

As we can cancel the initial fraction we see that these loci have the same radical axis as did the original pair \( \mathcal{C}_1 \) and \( \mathcal{C}_2 \). For this reason all the loci considered are said to be \textit{coaxal}.

**Exercises**

7.1 Prove that a circle cannot have more than one centre. [Hint. If \( O \) and \( O_1 \) are both centres, consider the intersection of \( OO_1 \) with the circle.]

7.2 Give an alternative proof of 7.2.1(iv) by showing that if \( (x - k)^2 + y^2 = k^2 \), where \( k > 0 \), then \( x \geq 0 \).

7.3 Prove that if the point \( X \) is interior to the circle \( (O;k) \), \( l \) is a line containing \( X \), and \( M = \pi_l(X) \), then \( M \) is also an interior point of this circle. Deduce that \( l \) is a secant line. Show too that if \( Y \) is also interior to this circle, then every point of the segment \( [X,Y] \) is also interior.

7.4 Show that if \( A, B, C \) are non-collinear points, there is a unique circle to which the side-lines \( BC, CA, AB \) are all tangents.

7.5 Let \( Z_1 \equiv (x_1,0), Z_2 \equiv (x_2,0) \) and \( Z_3 \equiv (x_3,0) \) be distinct fixed collinear points and \( Z_3 \) not the mid-point of \( Z_1 \) and \( Z_2 \). For \( W \not\in Z_1Z_2 \) let \( l \) be the mid-line of \( |Z_2WZ_1| \). Find the locus of \( W \) such that either \( l \), or the line through \( W \) perpendicular to \( l \), passes through \( Z_3 \).

7.6 Show that the locus of mid-points of chords of a circle on parallel lines is a diameter.

7.7 Show that if two tangents to a circle are parallel, then their points of contact are at the end-points of a diameter.

7.8 Show that if each of the side-lines of a rectangle is a tangent to a given circle, then it must be a square.

7.9 Consider the circle \( \mathcal{C}(O;a) \) and point \( Z_1 \equiv (x_1,0) \) where \( x_1 > a > 0 \), so that \( Z_1 \) is an exterior point which lies on the diametral line \( AB \), where \( A \equiv (a,0), B \equiv (-a,0) \). Show that for all points \( Z \equiv (x,y) \) on the circle,

\[ |Z_1,A| \leq |Z_1,Z| \leq |Z_1,B|. \]
7.10 For $0 < a < b$, suppose that $A \equiv (0, a), B \equiv (0, b)$. Show that the circles $C(A; a)$ and $C(B; b)$ both have the axis $OI$ as a tangent at the point $O$, and that $A \in [O, B]$. Verify that every point of $C(A; a)$, other than $O$, is an interior point for $C(B; b)$. [Hint. Consider the equations of $C(A; a)$ and $C(B; b)$.] 

7.11 Use Ex.6.3 to establish the equation of the mid-line $l$ in 7.3.1 when $P_1$ and $P_2$ are not diametrically opposite.
8

Translations; axial symmetries; isometries

COMMENT. In this chapter we introduce translations and develop them and axial symmetries. These will be useful in later chapters. It is more convenient to frame our proofs for isometries generally.

8.1 TRANSLATIONS AND AXIAL SYMMETRIES

8.1.1 Definition. Given points $Z_1, Z_2 \in \Pi$, we define a translation $t_{Z_1, Z_2}$ to be a function $t_{Z_1, Z_2} : \Pi \to \Pi$ such that, for all $Z \in \Pi$, $t_{Z_1, Z_2}(Z) = W$ where $mp(Z_1, W) = mp(Z_2, Z)$.

Translations have the following properties:-

(i) If $Z_1 \equiv (x_1, y_1)$ $Z_2 \equiv (x_2, y_2)$ $Z \equiv (x, y)$, $W \equiv (u, v)$, then $t_{Z_1, Z_2}(Z) = W$ if and only if

$$u = x + x_2 - x_1, \quad v = y + y_2 - y_1.$$ 

(ii) In all cases $|t_{Z_1, Z_2}(Z_3), t_{Z_1, Z_2}(Z_4)| = |Z_3, Z_4|$, so that each translation preserves all distances.

(iii) For each $W \in \Pi$ the equation $t_{Z_1, Z_2}(Z) = W$ has a solution in $Z$, so that each translation is an onto function.

(iv) Each translation $t_{Z_1, Z_2}$ has an inverse function $t_{Z_1, Z_2}^{-1} = t_{Z_2, Z_1}$.

(v) The translation $t_{Z_1, Z_1}$ is the identity function on $\Pi$. 

Geometry with Trigonometry
http://dx.doi.org/10.1016/B978-0-12-805066-8.50008-2
© 2016 Elsevier Ltd. All rights reserved.
(vi) If \( Z_1 \neq Z_2, Z \not\in Z_1Z_2 \) and \( W = t_{Z_1Z_2}(Z) \), then \([Z_1, Z_2, W, Z]\) is a parallelogram.

**Proof.**

(i) For

\[
\mp(Z_1, W) \equiv \left( \frac{1}{2}(x_1 + u), \frac{1}{2}(y_1 + v) \right), \quad \mp(Z_2, Z) \equiv \left( \frac{1}{2}(x_2 + x), \frac{1}{2}(y_2 + y) \right)
\]

and these are equal if and only if \( u = x + x_2 - x_1, v = y + y_2 - y_1 \).

(ii) For if \( W_3 = t_{Z_1Z_2}(Z_3) \), \( W_4 = t_{Z_1Z_2}(Z_4) \), then

\[
u_4 - v_3 = x_4 + x_2 - x_1 - (x_3 + x_2 - x_1) = x_4 - x_3,
\]

\[
v_4 - v_3 = y_4 + y_2 - y_1 - (y_3 + y_2 - y_1) = y_4 - y_3.
\]

It follows that \( |Z_3, Z_4| = |W_3, W_4| \).

(iii) By (i) the equation \( t_{Z_1Z_2}(Z) = W \) has the solution given by \( x = u + x_1 - x_2, y = v + y_1 - y_2 \).

(iv) By (ii) and (iii) the equation \( t_{Z_1Z_2}(Z) = W \) has a unique solution and this is denoted by \( Z = t_{Z_1Z_2}^{-1}(W) \). The correspondence from \( \Pi \) to \( \Pi \) given by \( W \to Z \) is the inverse of \( t_{Z_1Z_2} \) and is a function. As by the proof of (iii)

\[
x = u + x_1 - x_2, y = v + y_1 - y_2,
\]

by (i) this inverse function is \( t_{Z_2Z_1} \).

(v) If \( Z_1 = Z_2 \), in (i) we have \( u = x + x_1 - x_1 = x, v = y + y_1 - y_1 = y \).

(vi) We denote by \( T \) the common mid-point \( \mp(Z_1, W) = \mp(Z_2, Z) \). First we note that \( W \neq Z \), as \( \mp(Z_1, Z) = \mp(Z_2, Z) \) would imply \( Z_1 = Z_2 \). As \( Z \not\in Z_1Z_2 \), we have \( T \not\in Z_1Z_2 \) and hence \( W \not\in Z_1Z_2 \). It follows that \( T \not\in ZW \) as otherwise we would have \( Z_1 \in ZW, Z_2 \in ZW \) and so \( Z \in Z_1Z_2 \). The triangles \([Z_1, T, Z_2], [W, T, Z]\) are congruent in the correspondence \((Z_1, T, Z_2) \to (W, T, Z)\) by the SAS-principle. Hence the alternate angles \( \angle WZ_1Z_2, \angle Z_1WZ \) have equal degree-measures and so \( Z_1Z_2 \parallel WZ \). Similarly \( Z_1Z \parallel Z_2W \).

Axial symmetries have the following properties:

(i) In all cases \( |s_i(Z_3), s_i(Z_4)| = |Z_3, Z_4| \), so that each axial symmetry preserves all distances.

(ii) Each axial symmetry \( s_i \) has an inverse function \( s_i^{-1} = s_i \).

**Proof.**

(i) We note that by 6.6.1,

\[
s_i(Z_3)
\]

\[
\equiv \left( \frac{1}{a^2 + b^2} \left[ (b^2 - a^2)x_3 - 2aby_3 - 2ac \right], \frac{1}{a^2 + b^2} \left[ -2abx_3 - (b^2 - a^2)y_3 - 2bc \right] \right),
\]

\[
s_i(Z_4)
\]

\[
\equiv \left( \frac{1}{a^2 + b^2} \left[ (b^2 - a^2)x_4 - 2aby_4 - 2ac \right], \frac{1}{a^2 + b^2} \left[ -2abx_4 - (b^2 - a^2)y_4 - 2bc \right] \right),
\]
and thus
\[
|s_l(Z_3), s_l(Z_4)|^2 = \frac{1}{(a^2 + b^2)^2} \left\{ [(b^2 - a^2)(x_3 - x_4) - 2ab(y_3 - y_4)]^2 \\
+ [-2ab(x_3 - x_4) - (b^2 - a^2)(y_3 - y_4)]^2 \right\} \\
= \frac{1}{(a^2 + b^2)^2} \left\{ [(b^2 - a^2)^2 + 4a^2b^2][(x_3 - x_4)^2 + (y_3 - y_4)^2] \\
+ [-4ab + 4ab](b^2 - a^2)(x_3 - x_4)(y_3 - y_4) \right\} \\
= (x_3 - x_4)^2 + (y_3 - y_4)^2.
\]

(ii) For if \( m \) is the line through \( Z \) which is perpendicular to \( l \) and \( W = s_l(Z) \), then \( W \in m \) and so \( \pi_l(W) = \pi_l(Z) \). Then \( \pi_l(W) = mp(W, Z) \) so \( Z = s_l(W) \). This shows that the function \( s_l \) is its own inverse.

### 8.2 ISOMETRIES

#### 8.2.1

**Definition** A function \( f : \Pi \to \Pi \) which satisfies \( |Z_1, Z_2| = |f(Z_1), f(Z_2)| \) for all points \( Z_1, Z_2 \in \Pi \), is called an isometry of \( \Pi \).

Each translation and each axial symmetry is an isometry.

**Proof.** This follows from 8.1.1.

Each isometry \( f \) has the following properties:-

(i) The function \( f : \Pi \to \Pi \) is one-one.

(ii) For all \( Z_1, Z_2 \in \Pi \), \( f([Z_1, Z_2]) = [f(Z_1), f(Z_2)] \), so that each segment is mapped onto a segment, with the end-points corresponding.

(iii) For all distinct points \( Z_1, Z_2 \in \Pi \), \( f([Z_1, Z_2]) = [f(Z_1), f(Z_2)] \), so that each half-line is mapped onto a half-line, with the initial points corresponding.

(iv) For all distinct points \( Z_1, Z_2 \in \Pi \), \( f(Z_1Z_2) = f(Z_1)f(Z_2) \), so that each line is mapped onto a line. If \( f(Z) \in f(Z_1)f(Z_2) \) then \( Z \in Z_1Z_2 \).

(v) If \( Z_1, Z_2, Z_3 \) are noncollinear points, then \( f([Z_1, Z_2, Z_3]) \equiv [f(Z_1), f(Z_2), f(Z_3)] \).

(vi) Let \( Z_3 \not\in l \) and \( \mathcal{H}_1, \mathcal{H}_2 \) be the closed half-planes with common edge \( l \), with \( Z_3 \in \mathcal{H}_1 \). Let \( \mathcal{H}_3, \mathcal{H}_4 \) be the closed half-planes with common edge \( f(l) \), with \( f(Z_3) \in \mathcal{H}_3 \). Then \( f(\mathcal{H}_1) \subset \mathcal{H}_3, f(\mathcal{H}_2) \subset \mathcal{H}_4 \).

(vii) The function \( f : \Pi \to \Pi \) is onto.

(viii) In (vi), \( f(\mathcal{H}_1) = \mathcal{H}_3, f(\mathcal{H}_2) = \mathcal{H}_4 \).
(ix) If \( l \) and \( m \) are intersecting lines, then \( f(l) \) and \( f(m) \) are intersecting lines. If \( l \) and \( m \) are parallel lines, then \( f(l) \) and \( f(m) \) are parallel lines.

(x) If the points \( Z_1, Z_2 \) and \( Z_3 \) are non-collinear, then

\[
|\angle Z_2 Z_1 Z_3| = |\angle f(Z_2)f(Z_1)f(Z_3)|.
\]

(xi) If \( l \) and \( m \) are perpendicular lines, then \( f(l) \perp f(m) \).

(xii) If a point \( Z \) has Cartesian coordinates \((x, y)\) relative to the frame of reference \( \mathcal{F} = ([O, I], [O, J]) \), then \( f(Z) \) has Cartesian coordinates \((x, y)\) relative to the frame of reference \( ([f(O), f(I)], [f(O), f(J)]) \).

**Proof.**

(i) If \( Z_1 \neq Z_2 \) then \( |Z_1, Z_2| > 0 \) so that \( |f(Z_1), f(Z_2)| > 0 \), and so \( f(Z_1) \neq f(Z_2) \).

(ii) If \( Z_1 = Z_2 \) the result is trivial, so suppose that \( Z_1 \neq Z_2 \). Then for all \( Z \in [Z_1, Z_2] \), we have \( [Z_1, Z] + [Z, Z_2] = [Z_1, Z_2] \) and so \( |f(Z_1), f(Z)| + |f(Z), f(Z_2)| = |f(Z_1), f(Z_2)| \).

It follows by 3.1.2 and 4.3.1 that \( f(Z) \in [f(Z_1), f(Z_2)] \) and so \( f([Z_1, Z_2]) \subset [f(Z_1), f(Z_2)] \).

Next let \( W \in [f(Z_1), f(Z_2)] \). Then \( |f(Z_1), W| \leq |f(Z_1), f(Z_2)| = |Z_1, Z_2| \). Choose the point \( Z \in [Z_1, Z_2] \) so that \( |Z_1, Z| = |f(Z_1), W| \); as \( |Z_1, Z| \leq |Z_1, Z_2| \) then \( Z \in [Z_1, Z_2] \). Moreover \( |f(Z_1), f(Z)| = |Z_1, Z| = |f(Z_1), W| \). Then \( f(Z) \) and \( W \) are both in \( [f(Z_1), f(Z_2)] \) and at the same distance from \( f(Z_1) \) so \( f(Z) = W \). Thus \( W \) is a value of \( f \) at some point of \( [Z_1, Z_2] \). Hence \( f([Z_1, Z_2]) = [f(Z_1), f(Z_2)] \).

(iii) By (i) \( f(Z_1) \neq f(Z_2) \). Suppose that \( Z \in [Z_1, Z_2] \). Then either \( Z \in [Z_1, Z_2] \) or \( Z \in [Z_1, Z] \). It follows from part (ii) of the present theorem, that then either \( f(Z) \in [f(Z_1), f(Z_2)] \) or \( f(Z) \in [f(Z_1), f(Z)] \). Thus \( f(Z) \in [f(Z_1), f(Z_2)] \) and so \( f([Z_1, Z_2]) \subset [f(Z_1), f(Z_2)] \).

If \( W \in [f(Z_1), f(Z_2) \) choose \( Z \in [Z_1, Z_2] \) so that \( |Z_1, Z| = |f(Z_1), W| \). Then by the last paragraph \( f(Z) \in [f(Z_1), f(Z_2)] \) and as \( |f(Z_1), f(Z)| = |f(Z_1), W| \), we have \( f(Z) = W \). Thus \( W \) is a value of \( f \) at some point of \( [Z_1, Z_2] \). Hence \( f([Z_1, Z_2]) = [f(Z_1), f(Z_2)] \).
(iv) Take $Z_3 \neq Z_1$ so that $Z_1 \in [Z_2, Z_3]$. Then $Z_1Z_2 = [Z_1, Z_2] \cup [Z_1, Z_3]$. Hence
\[
f(Z_1Z_2) = f([Z_1, Z_2] \cup [Z_1, Z_3]) = [f(Z_1), f(Z_2)] \cup [f(Z_1), f(Z_3)] = f(Z_1)f(Z_2),
\]
as $f(Z_1) \in [f(Z_2), f(Z_3)]$.

If $f(Z) \in f(Z_1)f(Z_2)$, then by the foregoing there is a point $Z_4 \in Z_1Z_2$ such that $f(Z_4) = f(Z)$ and then as $f$ is one-one $Z = Z_4 \in Z_1Z_2$.

(v) For
\[
|Z_2, Z_3| = |f(Z_2), f(Z_3)|, |Z_3, Z_1| = |f(Z_3), f(Z_1)|, |Z_1, Z_2| = |f(Z_1), f(Z_2)|,
\]
so by the SSS-principle, these triangles are congruent in the correspondence
\[
(Z_1, Z_2, Z_3) \rightarrow (f(Z_1), f(Z_2), f(Z_3)).
\]

(vi) Suppose that $f(H_1)$ is not a subset of $H_3$. Then there is some $Z_4 \in H_1$ such that $f(Z_4) \in H_3$, $f(Z_4) \notin f(l)$. Then $f(Z_3)$ and $f(Z_4)$ are on opposite sides of $f(l)$, so there is a point $W$ on both $f(l)$ and $[f(Z_3), f(Z_4)]$. By (ii) there is a point $Z \in [Z_3, Z_4]$ such that $f(Z) = W$, and then by (i) and (iv) $Z \in l$. But this implies that $Z_4 \notin H_1$ and so gives a contradiction. Hence $f(H_1) \subset H_3$ and by a similar argument $f(H_2) \subset H_4$.

(vii) Take distinct points $Z_1, Z_2$ in $\Pi$. If $W \in f(Z_1)f(Z_2)$, then by (iv) $f(Z) = W$ for some $Z \in Z_1Z_2$ and so $W$ is a value of $f$.

![Figure 8.3](image-url)

Suppose then that $W \notin f(Z_1)f(Z_2)$ and let $H_3$ be the closed half-plane with edge $f(Z_1)f(Z_2)$ which contains $W$. Let $H_1$ be the closed half-plane with edge $Z_1Z_2$ such that by (vi) $f(H_1) \subset H_3$. Take a point $Z \in H_1$ such that
\[
\angle Z_2Z_1Z = \angle f(Z_2)f(Z_1)W \quad \text{and} \quad |Z_1, Z| = |f(Z_1), W|.
\]
Then by the SAS-principle $[Z_1, Z_2, Z] \equiv [f(Z_1), f(Z_2), W]$, and so by (v) $[f(Z_1), f(Z_2), f(Z)] \equiv [f(Z_1), f(Z_2), W]$. In particular
\[
\angle f(Z_2)f(Z_1)f(Z) = \angle f(Z_2)f(Z_1)W.
\]
As $f(Z) \in H_3$, $W \in H_3$ we then have $f(Z) \in f(Z_1), W$. But by the congruence we also have $|f(Z_1), f(Z)| = |f(Z_1), W|$. It follows that $f(Z) = W$ and so $W$ is a value of $f$. 

Sec. 8.2 Isometries 125
(viii) Let \( W \in \mathcal{H}_3 \). Then by (vii) \( W = f(Z) \) for some \( Z \in \Pi \). If \( W \in f(l) \) then by (iv) \( Z \in l \subset \mathcal{H}_1 \). If \( W \notin f(l) \) then \( W \notin \mathcal{H}_4 \) and by (vi) we cannot have \( Z \in \mathcal{H}_1 \) as that would imply \( W \in \mathcal{H}_4 \). Thus again \( Z \in \mathcal{H}_1 \). In both cases \( W \) is a value \( f(Z) \) for some \( Z \in \mathcal{H}_1 \).

(ix) By part (iv) \( f(l), f(m) \) are lines. If \( Z \) belongs to both \( l \) and \( m \), then \( f(Z) \) belongs to both \( f(l) \) and \( f(m) \) so these have a point in common.

On the other hand, if \( l \parallel m \) suppose first that \( l = m \). Then \( f(l) = f(m) \) and so \( f(l) \parallel f(m) \). Next suppose that \( l \neq m \); then \( l \cap m = \emptyset \). We now must have \( f(l) \cap f(m) = \emptyset \), as if \( W \) were on both \( f(l) \) and \( f(m) \), by (iv) we would have \( W = f(Z) \) for some \( Z \in l \), \( W = f(Z_0) \) for some \( Z_0 \in m \). But by (i) \( Z = Z_0 \) so we would have \( Z \) on both \( l \) and \( m \).

(x) By (v) the triangles \([Z_1, Z_2, Z_3], [f(Z_1), f(Z_2), f(Z_3)]\) are congruent, and so corresponding angles have equal degree-measures.

(xi) If \( l \) and \( m \) are perpendicular, let \( Z_1 \) be their point of intersection, and let \( Z_2, Z_3 \) be other points on \( l \) and \( m \) respectively. Then as in part (x), \( \angle Z_2 Z_1 Z_3 \) is a right-angle and so its image is also a right-angle.

(xii) For any line \( l \) and any point \( Z \) we recall that \( \pi_l(Z) \) denotes the foot of the perpendicular from \( Z \) to \( l \). For any point \( Z \in \Pi \), let \( U = \pi_{O,l}(Z) \) and \( V = \pi_{O,l}(Z) \). Let \( O' = f(O), I' = f(I), J' = f(J) \). Then \( O' \neq I', O' \neq J' \) and \( O'I' \perp O'J' \) so that we can take \( ([O', I'], [O', J']) \) as a frame of reference. Let \( \mathcal{H}_1, \mathcal{H}_2 \) be the half-planes with edge \( OI \), with \( J \in \mathcal{H}_1 \), and \( \mathcal{H}_3, \mathcal{H}_4 \) the half-planes with edge \( OJ \), with \( I \in \mathcal{H}_3 \). Similarly let \( \mathcal{H}'_1, \mathcal{H}'_2 \) be the half-planes with edge \( O'I' \), with \( J' \in \mathcal{H}'_1 \), and \( \mathcal{H}'_3, \mathcal{H}'_4 \) the half-planes with edge \( O'J' \), with \( I' \in \mathcal{H}'_3 \).

![Figure 8.4](image)

If \((x, y)\) are the Cartesian coordinates of \( Z \) relative to \((O, I, O, J)\), then

\[
x = \begin{cases} 
|O, U|, & \text{if } Z \in \mathcal{H}_3, \\
-|O, U|, & \text{if } Z \in \mathcal{H}_4.
\end{cases}
\]

But if \( Z' = f(Z), U' = f(U) \) we have \( U' \in O'I' \), and if \( Z \notin OI \) we have \( ZU \perp OI \) and hence \( Z'U' \perp O'I' \). It follows that \( U' = \pi_{O'I'}(Z') \). Moreover \( f(\mathcal{H}_3) = \mathcal{H}'_3, f(\mathcal{H}_4) = \mathcal{H}'_4 \).
\( \mathcal{H}_3' \). Then if \((x',y')\) are the Cartesian coordinates of \(Z'\) relative to \([O',I', [O',J']\), when \(Z \in \mathcal{H}_3\) we have \(Z' \in \mathcal{H}_3'\) and so
\[
x' = |O', \pi_{O'V}(Z')| = |O', U'| = |O, U| = x.
\]
Similarly when \(Z \in \mathcal{H}_4\) we have \(Z' \in \mathcal{H}_4'\) and so
\[
x' = -|O', \pi_{O'V}(Z')| = -|O', U'| = -|O, U| = x.
\]
Thus \(x' = x\) in all cases, and by a similar argument \(y' = y\).

### 8.2.2

If \(l = \text{ml}(\overline{BAC})\), then \(s_l([A,B]) = [A,C]\) and \(s_l([A,C]) = [A,B]\).

**Proof.** We prove \(s_l([A,B]) = [A,C]\) as the other then follows. As \(A \in l\) we have \(s_l(A) = A\) and so by 8.2.1(iii) \(s_l([A,B]) = [A,D]\) for some point \(D\).

Suppose first that \(A,B,C\) are collinear. When \(C \in [A,B]\) we have \(l = AB\), and so \(s_l(P) = P\) for all \(P \in [A,B]\). As \(A,B = [A,C]\) the conclusion is then immediate. On the other hand when \(A \in [B,C]\) so that \(\overline{BAC}\) is straight, \(l\) is the perpendicular to \(AB\) at \(A\). Then if \(A = \text{mp}(B,D)\) we have \(s_l([A,B]) = [A,D]\), and \(A,D = [A,C]\) as \(D \in [A,C]\).

Finally suppose that \(A,B,C\) are non-collinear. Now take \(D \in [A,C]\) so that \(A,D = [A,B]\). If \(M = \text{mp}(B,D)\) by 4.1.1(iv) we have that \(l = AM\) and as \(s_l(B) = D\) then \(s_l([A,B]) = [A,D] = [A,C]\).

### 8.3 TRANSFORMATION OF FRAME OF REFERENCE

**NOTATION.** By using 8.2.1(iii), (vi) and (xi), we showed in 8.2.1(xii) that for any frame of reference \(\mathcal{F} = ([O,I], [O,J])\) and any isometry \(f\), \(\mathcal{F}' = ([f(O), f(I)], [f(O), f(J)])\) is also a frame of reference, and that Cartesian coordinates of \(Z\) relative to \(\mathcal{F}\) are also Cartesian coordinates of \(f(Z)\) relative to \(\mathcal{F}'\). We denote \(\mathcal{F}'\) by \(f(\mathcal{F})\).

For any frame of reference \(\mathcal{F} = ([O,I], [O,J])\), let \(Z_0 \equiv \mathcal{F} (x_0,y_0)\) and \(\mathcal{F}' = t_{OZ_0}(\mathcal{F})\). Then if \(Z \equiv \mathcal{F} (x,y)\) we have \(Z \equiv \mathcal{F}' (x-x_0,y-y_0)\).

**Proof.** By 8.2.1(xii), \(t_{OZ_0}(Z)\) has coordinates \((x,y)\) relative to \(\mathcal{F}'\), and by 8.1.1(i) it also has coordinate \((x+x_0,y+y_0)\) relative to \(\mathcal{F}\). Thus for all \((x,y) \in \mathbb{R} \times \mathbb{R}\) the point with coordinates \((x+x_0,y+y_0)\) relative to \(\mathcal{F}\) has coordinates \((x,y)\) relative to \(\mathcal{F}'\). On replacing \((x,y)\) by \((x-x_0,y-y_0)\), we conclude that the point with coordinates \((x,y)\) relative to \(\mathcal{F}\) has coordinates \((x-x_0,y-y_0)\) relative to \(\mathcal{F}'\).
Exercises

8.1 If $\mathcal{T}$ is the set of all translations of $\Pi$, show that $(\mathcal{T}, \circ)$ is a commutative group.

8.2 If $\mathcal{I}$ is the set of all isometries of $\Pi$, show that $(\mathcal{I}, \circ)$ is a group.

8.3 Given any half-lines $[A, B], [C, D]$ show that there is an isometry $f$ which maps $[A, B]$ onto $[C, D]$.

8.4 Show that each of the following concepts is an isometric invariant: interior region of an angle-support, triangle, dividing a pair of points in a given ratio, mid-point, centroid, circumcentre, orthocentre, mid-line, incentre, parallelogram, rectangle, square, area of a triangle, circle, tangent to a circle.

8.5 For any line $l$, $s_{l}[C(O; k)] = C(s_{l}(O); k)$ so that, in particular, if $O \in l$ then $s_{l}[C(O; k)] = C(O; k)$. 
COMMENT. In this chapter we go on to deal fully with reflex-angles as well as with wedge and straight ones, we define the cosine and sine of an angle and we deal with addition of angles. As a vitally convenient aid to identifying the two angles with a given support $|BAC|$, we start by introducing the notion of the indicator of an angle.

9.1 INDICATOR OF AN ANGLE

9.1.1

Definition. If $\alpha$ is an angle with support $|BAC|$, we call the other angle with support $|BAC|$ the co-supported angle for $\alpha$, and denote it by $\text{co} - \text{sp} \ \alpha$.

Figure 9.1. Co-supported angle.

Figure 9.2. Angle indicators.
**Definition.** Referring to 2.3.3, for each angle support $|BAC|$ let $l = ml(|BAC|)$ as in 3.6 and 4.1.1. When $A \notin BC$, we call $l \cap \IR(|BAC|)$ and $l \cap \ER(|BAC|)$ the **indicators** of the wedge-angle ($|BAC, \IR(|BAC|)$) and of the reflex-angle ($|BAC, \ER(|BAC|)$), respectively. When $A \in [B,C]$ we call $l \cap IR(|BAC|)$ and $l \cap ER(|BAC|)$ the indicators of the straight-angles ($|BAC, IR(|BAC|)$), respectively. The null-angle with support $|BAB|$ has indicator $[A,B]$. The full-angle with support $|BAB|$ has indicator $[A,D]$ where $D \neq A$ and $A \in [B,D]$. In each case an indicator is a half-line of $l$ with initial point the vertex $A$. We denote the indicator of an angle $\alpha$ by $i(\alpha)$.

**COMMENT.** The first use we make of the concept of indicator is in defining the cosine and sine of any angle.

### 9.2 COSINE AND SINE OF AN ANGLE

**Definition.** Consider an angle $\alpha$ with support $|BAC|$ such that the indicator $i(\alpha)$ lies in a closed half-plane $H_1$ with edge $AB$. Then we define $\cos \alpha$ and $\sin \alpha$ as follows. Take any point $P \neq A$ on $[A,C]$, let $Q \in [A,B]$ be such that $|A,Q| = |A,P|$ and $R \in H_1$ be such that $|A,R| = |A,P|$ and $AR \perp AB$.

Let $U,V$ be the feet of the perpendiculars from $P$ to $AB = AQ$ and $AR$ respectively. Then we define

$$
\cos \alpha = \frac{|A,P| - |Q,U|}{|A,P|}, \quad \sin \alpha = \frac{|A,P| - |R,V|}{|A,P|}.
$$

It follows from this definition that if $H_2$ is the other half-plane with edge $AB$ and if we take $T \in H_2$ so that $|A,T| = |A,P|$ and $AT \perp AB$, then

$$
\cos(\co - \sp \alpha) = \frac{|A,P| - |Q,U|}{|A,P|}, \quad \sin(\co - \sp \alpha) = \frac{|A,P| - |T,V|}{|A,P|}.
$$

**COMMENT.** Two comments on this definition are in order. First we note that when $A,B,C$ are collinear, $H_1$ and $H_2$ are not uniquely determined above but are interchangeable with each other, so that the angles $\alpha$ and $\co - \sp \alpha$ are not uniquely determined. Our second comment is that to show that $\cos \alpha$, $\sin \alpha$ are well-defined it is first necessary to use the ratio results for triangles to show that the values of $\cos \alpha$ and $\sin \alpha$ do not depend on the particular point $P \in [A,C]$ taken, and then to show that if the arms $[A,B]$ and $[A,C]$ are interchanged the outcome is unchanged.
To help us in our study of angles, it is convenient to fit a frame of reference to the situation in the definition. We take $O = A, I = B$ and $J \neq O$ a point in $\mathcal{H}_1$ so that $OI \perp OJ$. We let $\mathcal{H}_3, \mathcal{H}_4$ be the closed half-planes with edge $OJ$, with $I \in \mathcal{H}_3$.

With $k = |A, P| = |O, P|$, let $Q$ be the point on $[O, I] = [A, B]$ such that $|O, Q| = k$, and let $R$ be the point on $[O, J]$ such that $|O, R| = k$. Choose $S, T$ so that $O = mp(Q, S), O = mp(R, T)$.

![Figure 9.4](image)

**The cosine and sine of an angle are well-defined.**

**Proof.**

(i) When $A, B$ and $C$ are collinear there are two cases to be considered. One case is when $A \in [B, C]$ so that $[BAC]$ is straight. Then each of $\alpha$, $\cos - \text{sp} \alpha$ is a straight-angle and as $P = S$, we have $U = S$, $V = A$ and so

$$\cos \alpha = \cos(\cos - \text{sp} \alpha) = -1, \quad \sin \alpha = \sin(\cos - \text{sp} \alpha) = 0.$$  

A second case is when $C \in [A, B]$ so that one of $\alpha$, $\cos - \text{sp} \alpha$ is a null-angle with indicator $[A, B]$ and the other is a full-angle with indicator $[A, B_1]$ where $A$ is between $B$ and $B_1$. Both of the indicators are in $\mathcal{H}_1$ and $\mathcal{H}_2$, but as $P = Q$ we have $U = Q, V = A$ and so

$$\cos \alpha = \cos(\cos - \text{sp} \alpha) = 1, \quad \sin \alpha = \sin(\cos - \text{sp} \alpha) = 0.$$  

Thus in neither case does the ambiguity affect the outcome.

(ii) We now use the ratio results for triangles to show that the values of $\cos \alpha$ and $\sin \alpha$ do not depend on the particular point $P \in [A, C]$ chosen. Take $k_1 > 0$ and let $P_1, Q_1, R_1$ be the points in $[O, P], [O, Q], [O, R]$ respectively, each at a distance $k_1$ from $O$. Let $U_1 = \pi_{OJ}(P_1), V_1 = \pi_{OJ}(P_1)$.

Suppose first that $P \notin OI, P \notin OJ$. As $PU \parallel P_1U_1$, by 5.3.1

$$\frac{|O, U|}{|O, U_1|} = \frac{|O, P|}{|O, P_1|},$$

and so

$$\frac{|O, U|}{k} = \frac{|O, U_1|}{k_1}.$$  

Now if $P \in \mathcal{H}_3$ so that $U \in [Q, O]$ and so $|O, U| = k - |Q, U|$, by 2.2.3(iv) $P_1 \in \mathcal{H}_3$ and similarly $|O, U_1| = k_1 - |Q_1, U_1|$. On inserting this we get that

$$\frac{k - |Q, U|}{k} = \frac{k_1 - |Q_1, U_1|}{k_1}.$$
When instead $P \in H_4$, we have $O \in [Q,U]$ so $|O,U| = |Q,U| - k$ and similarly $|O,U_1| = |Q_1,U_1| - k_1$. On inserting these we obtain

$$\frac{k - |Q,U|}{k} = \frac{k_1 - |Q_1,U_1|}{k_1}$$

again.

When $P \in OI$ we have either $P = Q$ or $P = S$. When $P = Q$, we have $P_1 = Q_1$ and the formula checks out. It checks out similarly in the cases when $P$ is $R$, $S$ or $T$.

By a similar proof we find that

$$\frac{k - |R,V|}{k} = \frac{k_1 - |R_1,V_1|}{k_1}.$$

Thus it makes no difference to the values of $\cos \alpha$ and $\sin \alpha$ if $P$ is replaced by $P_1$.

\[
\begin{align*}
\text{Figure 9.5.} & \\
\text{Figure 9.6.}
\end{align*}
\]

(iii) It remains to show that if the arms $[A,B]$ and $[A,C]$ are interchanged the outcome is unchanged. Let $l = \text{mid}QOP$ so that $s_l(OQ) = OP$ and $s_l(H_1)$ is a closed half-plane with edge $OP$. As $i(\alpha) \subset H_1$ we have $s_l(i(\alpha)) \subset s_l(H_1)$; but as $i(\alpha) \subset l$, $s_l(i(\alpha)) = i(\alpha)$ and thus $i(\alpha) \subset s_l(H_1)$. If $W = s_l(R)$ then $W \in s_l(H_1)$ and as $OQ \perp OR$ we have $OP \perp OW$. Moreover $X = s_l(U) = \pi_{OP}(Q)$ and $Y = s_l(V) = \pi_{OW}(Q)$ satisfy $|P,X| = |Q,U|$, $|W,Y| = |R,V|$. Hence

$$\frac{k - |P,X|}{k} = \frac{k - |Q,U|}{k}, \quad \frac{k - |W,Y|}{k} = \frac{k - |R,V|}{k}.$$

This completes the proof.

\subsection{Polar coordinates}

For $Z \neq O$, let $k = |O,Z|$ and the angle $\alpha$ have support $|OZ|$ and indicator $i(\alpha)$ in $H_1$. Then if $Z \equiv (x,y)$,

$$x = k \cos \alpha, \quad y = k \sin \alpha.$$
Proof. Let \( Q, R \) be the points where \( C(O; k) \) meets \([O, I]\) and \([O, J]\), respectively; then \( Q \) and \( R \) have Cartesian coordinates \((k, 0)\) and \((0, k)\), respectively. Let \( U, V \) be the feet of the perpendiculars from \( Z \) to the lines \( OI \) and \( OJ \), so that these have Cartesian coordinates \((x, 0)\) and \((0, y)\) respectively. Now \( O \equiv (0, 0) \) and \( Z \equiv (x, y) \) so by the distance formula \( (x - 0)^2 + (y - 0)^2 = k^2 \). Thus \( x^2 + y^2 = k^2 \), so that \( x^2 \leq k^2 \) and as \( k > 0 \) we have \( x \leq k \). Then by the distance formula
\[
|Q, U| = \sqrt{(k - x)^2 + (0 - 0)^2} = k - x,
\]
as \( k - x \geq 0 \), and similarly \( |R, V| = k - y \). Hence
\[
\cos \alpha = \frac{k - |Q, U|}{k} = \frac{k - (k - x)}{k} = \frac{x}{k},
\]
\[
\sin \alpha = \frac{k - |R, V|}{k} = \frac{k - (k - y)}{k} = \frac{y}{k}.
\]
Thus \( x = k \cos \alpha, y = k \sin \alpha \).

We refer to \( k \) and \( \alpha \) as polar coordinates of the point \( Z \) with respect to \( \mathcal{F} \).

9.2.3

With the notation of 9.2.1, let \( \alpha \) be an angle with support \( |IOP| = |QOP| \) and indicator \( i(\alpha) \) in \( \mathcal{A} \). Then we have the following properties:

(i) For all \( \alpha \), \( \cos^2 \alpha + \sin^2 \alpha = 1 \).

(ii) For \( P \in \mathcal{Q}_1 \), \( \cos \alpha \geq 0 \), \( \sin \alpha \geq 0 \); for \( P \in \mathcal{Q}_2 \), \( \cos \alpha \leq 0 \), \( \sin \alpha \geq 0 \); for \( P \in \mathcal{Q}_3 \), \( \cos \alpha \leq 0 \), \( \sin \alpha \leq 0 \); for \( P \in \mathcal{Q}_4 \), \( \cos \alpha \geq 0 \), \( \sin \alpha \leq 0 \).

Proof.

(i) As in the proof in 9.2.1,
\[
\cos \alpha = \pm \frac{|O, U|}{|O, P|}, \quad \sin \alpha = \pm \frac{|O, V|}{|O, P|}.
\]

Now when \( O, U, P, V \) are not collinear they are the vertices of a rectangle and so \( |O, V| = |U, P| \). Then by Pythagoras’ theorem
\[
|O, U|^2 + |U, P|^2 = |O, P|^2,
\]
and the result follows. It can be verified directly when \( P \) is any of \( Q, R, S, T \).

(ii) This follows directly from details in the proof in 9.2.1.

9.3 ANGLES IN STANDARD POSITION

9.3.1 Angles in standard position

COMMENT. The second use that we make of the concept of indicator of an angle is to identify angles with respect to a frame of reference.
Definition. We recall from 3.7 our extension of degree-measure to reflex-angles. Let \( \overline{QOP} \) be a non-straight support, and let \( \mathcal{H}_1, \mathcal{H}_2 \) be the closed-half planes with edge \( OQ \), with \( P \in \mathcal{H}_2 \). Let \( \alpha \) be the reflex angle with support \( \overline{QOP} \), so that \( i(\alpha) \subset \mathcal{H}_1 \). Let \( S \) be the point such that \( O = mp(Q,S) \). Let \( \beta \) be the wedge or straight angle with support \( \overline{SOP} \).

Then we defined the degree measure of \( \alpha \) by \( |\alpha| = 180 + |\beta| \). In particular if \( P = Q \), then \( \beta \) is a straight angle, \( \alpha \) is the full angle with support \( \overline{POP} = \overline{QQO} \) and indicator \( \overline{O,S} \), and \( |\alpha| = 360 \).

Definition. Given a frame of reference \( \mathcal{F} = (\overline{O,I}, \overline{O,J}) \), we denote by \( \mathcal{A}^*(\mathcal{F}) \) the set of angles \( \alpha \) with arm \( \overline{O,I} \) and with indicator \( i(\alpha) \subset \mathcal{H}_1 \). These angles are said to be in standard position with respect to \( \mathcal{F} \).
If $\alpha$ and $\gamma$ are different angles in $A^*(F)$, then $|\alpha|\nmid |\gamma|\nmid$.

**Proof.** This is evident if $\alpha$ and $\gamma$ are both wedge or straight angles and hence, by addition of 180, if they are both reflex or straight. If $\alpha$ is wedge or straight and $\gamma$ is reflex, then $|\alpha|\nmid \leq 180$, $|\gamma|\nmid > 180$.

**NOTATION.** Given any real number $x$ such that $0 \leq x \leq 360$, we denote the angle $\alpha \in A^*(F)$ with $|\alpha|\nmid = x$ by $x_F$. Thus the null, straight and full angles in $A^*(F)$ are denoted by $0_F$, $180_F$ and $360_F$, respectively.

### 9.3.2 Addition of angles

**COMMENT.** Given angles $\alpha, \beta \in A^*(F)$ we wish to define two closely related forms of addition, the first suited to angle measure as to be dealt with in Chapter 12 and the second suited to more general situations. As we make more use of the latter we employ for it the common symbol $+$, and $\oplus$ for the former. As $\alpha \oplus \beta$ is to be an angle we need to specify its support and its indicator; similarly for $\alpha + \beta$.

**Definition.** Let $\alpha, \beta$ be angles in $A^*(F)$ with supports $|QOP_1, |QOP_2$, respectively. Let $l$ be the midline of $|P_1OP_2$ and let $P_3 = s_l(Q)$. Then $\alpha \oplus \beta$ is an angle with support $|QOP_3$ for which $i(\alpha \oplus \beta) \subset H_1$, so that $\alpha \oplus \beta \in A^*(F)$. This identifies $\alpha \oplus \beta$ uniquely except when $P_3 = Q$; in this case both the null angle $0_F$ and the full angle $360_F$ have support $|QQQ$ and we define $\alpha \oplus \beta$ to be this full angle $360_F$ in every case except when $\alpha$ and $\beta$ are both null; in the latter case we define the sum to be this null angle $0_F$. We call $\alpha \oplus \beta$ the sum of the angles $\alpha$ and $\beta$.

![Figure 9.9. Addition of angles.](image)

**Figure 9.9. Addition of angles.**

For all angles $\alpha, \beta \in A^*(F)$,

(i) $\cos(\alpha \oplus \beta) = \cos \alpha \cos \beta - \sin \alpha \sin \beta$,

(ii) $\sin(\alpha \oplus \beta) = \sin \alpha \cos \beta + \cos \alpha \sin \beta$.

**Proof.** On using the notation of 7.3.1 and above, we have

$$a_1 = \cos \alpha, b_1 = \sin \alpha, a_2 = \cos \beta, b_2 = \sin \beta, a_3 = \cos(\alpha \oplus \beta), b_3 = \sin(\alpha \oplus \beta).$$
We note that in 7.3.1
\[(a_1 + a_2)^2 + (b_1 + b_2)^2 = 2(1 + a_1a_2 + b_1b_2),\]
as \[a_1^2 + b_1^2 = a_2^2 + b_2^2 = 1.\] Then, by 7.3.2, when \(P_1\) and \(P_2\) are not diametrically opposite,\
\[\cos(\alpha \oplus \beta) - \cos \alpha \cos \beta + \sin \alpha \sin \beta = \frac{(a_1 + a_2)^2 - (b_1 + b_2)^2 + 2(-a_1a_2 + b_1b_2)(1 + a_1a_2 + b_1b_2)}{2(1 + a_1a_2 + b_1b_2)},\]
and the numerator here is equal to\
\[a_1^2 + a_2^2 - b_1^2 - b_2^2 - 2a_1a_2 + 2b_1b_2 = 2a_1^2 + 2a_2^2 - 2 - 2a_1^2a_2^2 + 2(1 - a_1^2)(1 - a_2^2) = 0.\]

Similarly
\[\sin(\alpha \oplus \beta) - \sin \alpha \cos \beta - \cos \alpha \sin \beta = \frac{2(a_1 + a_2)(b_1 + b_2) - 2(a_1b_2 + a_2b_1)(1 + a_1a_2 + b_1b_2)}{2(1 + a_1a_2 + b_1b_2)},\]
and the numerator here is equal to twice\
\[a_1b_1 + a_2b_2 - a_1b_1(a_2^2 + b_2^2) - a_2b_2(a_1^2 + b_1^2) = 0.\]

When \(P_1\) and \(P_2\) are diametrically opposite,\
\[\cos(\alpha \oplus \beta) - \cos \alpha \cos \beta + \sin \alpha \sin \beta = b_1^2 - a_1^2 - a_1(-a_1) + b_1(-b_1) = 0,\]
\[\sin(\alpha \oplus \beta) - \sin \alpha \cos \beta - \cos \alpha \sin \beta = -2a_1b_1 - b_1(-a_1) - a_1(-b_1) = 0.\]

9.3.3 Modified addition of angles

**COMMENT.** In 9.3.2 we clearly exercised a choice in specifying what \(\alpha \oplus \beta\) should be when \(P_3 = Q\). The choice made there is what suits length of a circle and area of a disk which will be treated in Chapter 12, and that was the reason for the choice made. We now define modified addition \(\alpha + \beta\) of angles, which is easier to use.

**Definition.** Let \(\mathcal{A}(\mathcal{F}) = \mathcal{A}^*(\mathcal{F}) \setminus \{360\mathcal{F}\}\), so that \(\mathcal{A}(\mathcal{F})\) is the set of all non-full angles in \(\mathcal{A}^*(\mathcal{F})\). We denote by \(\angle_{\mathcal{F}} QOP = \angle_{\mathcal{F}} IOP\) the unique angle in \(\mathcal{A}(\mathcal{F})\) with support \(\overline{QOP} = \overline{IOP}\).

**Definition.** Let \(\alpha, \beta\) be angles in \(\mathcal{A}(\mathcal{F})\) with supports \(\overline{QOP}_1, \overline{QOP}_2\). Let \(l\) be the midline of \(\overline{P_1OP_2}\) and let \(P_3 = s_l(Q)\). Then \(\alpha + \beta\) is the angle in \(\mathcal{A}(\mathcal{F})\) with support \(\overline{QOP}_3\). Note that when \(P_3 = Q\) we have \(\alpha + \beta = 0\mathcal{F}\). We call \(\alpha + \beta\) the **modified sum** of the angles \(\alpha\) and \(\beta\).

For all \(\alpha, \beta \in \mathcal{A}(\mathcal{F})\),
\[\cos(\alpha + \beta) = \cos \alpha \cos \beta - \sin \alpha \sin \beta, \quad \sin(\alpha + \beta) = \sin \alpha \cos \beta + \cos \alpha \sin \beta.\]

**Proof.** This follows immediately from 9.3.2 as \(\cos 360\mathcal{F} = \cos 0\mathcal{F}, \sin 360\mathcal{F} = \sin 0\mathcal{F}\).
Modified addition of angles has the following properties:

(i) For all \( \alpha, \beta \in \mathcal{A}(\mathcal{F}) \), \( \alpha + \beta \) is uniquely defined and lies in \( \mathcal{A}(\mathcal{F}) \).

(ii) For all \( \alpha, \beta \in \mathcal{A}(\mathcal{F}) \), \( \alpha + \beta = \beta + \alpha \).

(iii) For all \( \alpha, \beta, \gamma \in \mathcal{A}(\mathcal{F}) \), \( (\alpha + \beta) + \gamma = \alpha + (\beta + \gamma) \).

(iv) For all \( \alpha \in \mathcal{A}(\mathcal{F}) \), \( \alpha + 0 = \alpha \).

(v) Corresponding to each \( \alpha \in \mathcal{A}(\mathcal{F}) \), there is a \( \beta \in \mathcal{A}(\mathcal{F}) \) such that \( \alpha + \beta = 0 \).

**Proof.**

(i) This is evident from the definition.

(ii) This is evident as the roles of \( P_1 \) and \( P_2 \) are interchangeable in the definition.

(iii) We note that by the last result

\[
\cos[(\alpha + \beta) + \gamma] = \cos(\alpha + \beta) \cos \gamma - \sin(\alpha + \beta) \sin \gamma
\]

and then

\[
\cos[(\alpha + \beta) + \gamma] = \cos \alpha \cos \beta - \sin \alpha \sin \beta \cos \gamma - \sin \alpha \cos \beta + \cos \alpha \sin \beta \sin \gamma,
\]

while

\[
\cos[\alpha + (\beta + \gamma)] = \cos \alpha \cos(\beta + \gamma) - \sin \alpha \sin(\beta + \gamma)
\]

\[
= \cos \alpha [\cos \beta \cos \gamma - \sin \beta \sin \gamma] - \sin \alpha [\sin \beta \cos \gamma + \cos \beta \sin \gamma],
\]

and these are equal. Similarly

\[
\sin[(\alpha + \beta) + \gamma] = \sin(\alpha + \beta) \cos \gamma + \cos(\alpha + \beta) \sin \gamma
\]

\[
= \sin \alpha \cos \beta + \cos \alpha \sin \beta \cos \gamma + \cos \alpha \cos \beta - \sin \alpha \sin \beta \sin \gamma,
\]

while

\[
\sin[\alpha + (\beta + \gamma)] = \sin \alpha \cos(\beta + \gamma) + \cos \alpha \sin(\beta + \gamma)
\]

\[
= \sin \alpha [\cos \beta \cos \gamma - \sin \alpha \sin \beta] + \cos \alpha [\sin \beta \cos \gamma + \cos \beta \sin \gamma],
\]

and these are equal. Thus \( (\alpha + \beta) + \gamma \) and \( \alpha + (\beta + \gamma) \) are angles in \( \mathcal{A}(\mathcal{F}) \) with the same cosine and the same sine and so by 9.2.2 they are equal.

(iv) When \( \beta = 0 \), in the definition we have \( P_2 = Q \) and then \( l \) is the midline of \( |QOP_1| \) and so \( P_3 = P_1 \). Thus \( \alpha \) and \( \alpha + 0 \) are both in \( \mathcal{A}(\mathcal{F}) \) and they have the same support, so they must be equal.

(v) Given any angle \( \alpha \in \mathcal{A}(\mathcal{F}) \) with support \( |QOP_1| \), let \( P_2 = s_{OQ}(P_1) \) and \( \beta \) be the angle in \( \mathcal{A}(\mathcal{F}) \) with support \( |QOP_2| \). Then \( l = OI \) is the midline of \( |P_1OP_2| \) and so in the definition \( P_3 = s_{Q}(Q) = Q \). Thus \( \alpha + \beta \) has support \( |QQQQ| \) and so it is \( 0 \).

**COMMENT.** The properties just listed show that \( (\mathcal{A}(\mathcal{F}), +) \) is a commutative group. Because of this the familiar properties of addition, subtraction and additive cancellation apply to it.
9.3.4 Subtraction of angles

**Definition.** For all \( \alpha \in \mathcal{A}(\mathcal{F}) \), we denote the angle \( \beta \) in 9.3.3(v) by \(-\alpha\). The difference \( \gamma - \alpha \) in \( \mathcal{A}(\mathcal{F}) \) is defined by specifying that \( \gamma - \alpha = \gamma + (-\alpha) \). In this way we deal with subtraction.

For all \( \alpha \in \mathcal{A}(\mathcal{F}) \),

\[
\cos(-\alpha) = \cos(\cos - \sp\alpha) = \cos \alpha, \quad \sin(-\alpha) = \sin(\cos - \sp\alpha) = -\sin \alpha.
\]

**Proof.** With \( P_2 \) as in the proof of 9.3.3(v), we have

\[
\cos(-\alpha) = \frac{k - |Q, U|}{k}, \quad \sin(-\alpha) = \frac{k - |R, V_1|}{k},
\]

and \( |R, V_1| = |T, V| = 2k - |R, V| \). We use this in conjunction with 9.2.1.

9.3.5 Integer multiples of an angle

**Definition.** For all \( n \in \mathbb{N} \) and all \( \alpha \in \mathcal{A}(\mathcal{F}) \), \( n\alpha \) is defined inductively by

\[
1\alpha = \alpha, \quad (n+1)\alpha = n\alpha + \alpha, \quad \text{for all} \quad n \in \mathbb{N}.
\]

We refer to \( n\alpha \) as integer multiples of the angle \( \alpha \).

For all \( \alpha \in \mathcal{A}(\mathcal{F}) \),

(i) \( \cos(2\alpha) = \cos^2 \alpha - \sin^2 \alpha = 2\cos^2 \alpha - 1 = 1 - 2\sin^2 \alpha \),

(ii) \( \sin(2\alpha) = 2\cos \alpha \sin \alpha \).

**Proof.** These are immediate by 9.3.3 and 9.2.3.

9.3.6 Standard multiples of a right-angle

The angles \( 90\mathcal{F}, 180\mathcal{F}, 270\mathcal{F} \) have the following properties:-
Sec. 9.4

Half angles

139

(i) \[
\cos 90_F = 0, \sin 90_F = 1, \cos 180_F = -1, \sin 180_F = 0, \cos 270_F = 0, \sin 270_F = -1.
\]

(ii) \[
2(90_F) = 180_F, 2(180_F) = 0_F \text{ so that } -180_F = 180_F, \text{ and } 90_F + 270_F = 0_F \text{ so that } 270_F = -90_F.
\]

(iii) For all \( \alpha \in \mathcal{A}(F) \),

\[
\cos(\alpha + 90_F) = -\sin \alpha, \sin(\alpha + 90_F) = \cos \alpha,
\]
\[
\cos(\alpha + 180_F) = -\cos \alpha, \sin(\alpha + 180_F) = -\sin \alpha,
\]
\[
\cos(\alpha + 270_F) = \sin \alpha, \sin(\alpha + 270_F) = -\cos \alpha.
\]

**Proof.**

(i) These follow immediately from 9.2.1.

(ii) These follow from 9.2.1 and 9.3.4.

(iii) These follow immediately from 9.3.3 and (i) of the present theorem.

9.4 HALF ANGLES

9.4.1

**Definition.** Given any angle \( \alpha \in \mathcal{A}(F) \) with support \( |QOP| \), its indicator \( i(\alpha) \) meets \( C(O; k) \) in a unique point \( P' \) which is in \( \mathcal{H}_1 \). Then the wedge or straight angle in \( \mathcal{A}(F) \) with support \( |QOP'| \) is denoted by \( \frac{1}{2}\alpha \) and is called a half-angle.

Given any angle \( \alpha \in \mathcal{A}(F) \), the equation \( 2\gamma = \alpha \) has exactly two solutions in \( \mathcal{A}(F) \), these being \( \frac{1}{2}\alpha \) and \( \frac{1}{2}\alpha + 180_F \).

**Proof.** In the definition we have \( \frac{1}{2}\alpha = \angle FQOP' \) and take \( P'' \) so that \( O = mp(P', P'') \). Let \( \beta = \angle FQOP'' \) so that \( \beta = \frac{1}{2}\alpha + 180_F \). Then \( s_{OP'}(Q) = P \) so that by 9.3.3, \( 2(\frac{1}{2}\alpha) = \alpha, 2\beta = \alpha \).

Now suppose that \( \gamma, \delta \in \mathcal{A}(F) \) and \( 2\gamma = 2\delta = \alpha \). Then \( \cos 2\delta = \cos 2\gamma \) so that \( 2\cos^2 \delta - 1 = 2\cos^2 \gamma - 1 \), and hence \( \cos \delta = \pm \cos \gamma \).

Then also \( \sin^2 \delta = \sin^2 \gamma \) so \( \sin \delta = \pm \sin \gamma \). Moreover \( \sin 2\delta = \sin 2\gamma \) so \( 2\sin \delta \cos \delta = 2\sin \gamma \cos \gamma \).

We first suppose that \( \alpha \neq 180_F \) so that \( \cos \alpha \neq -1 \) and so \( \cos \gamma \neq 0 \). Then if \( \cos \delta = \cos \gamma \) we must have \( \sin \delta = \sin \gamma \), and so \( \delta = \gamma \). Alternatively we must have \( \cos \delta = -\cos \gamma, \sin \delta = -\sin \gamma \) and so \( \delta = \gamma + 180_F \).
If \( \alpha = 180_\circ \) then \( \cos \delta = 0 \), so that \( \sin \delta = \pm 1 \) and so \( \delta \) is either \( 90_\circ \) or \( 270_\circ \).

**COMMENT.** Our definition of a half-angle is the standard one for the angles we deal with, but it would not suit angles which we do not consider, for example ones with degree-magnitude greater than 360. The latter are difficult to give an account of geometrically. For us \( \frac{1}{2}\alpha + \frac{1}{2}\beta \) and \( \frac{1}{2}(\alpha + \beta) \) need not be equal; we shall deal with such matters in 12.1.1. Because of this, there is a danger of error if half-angles are used incautiously.

For any angles \( \alpha, \beta \in \mathcal{A}(\mathcal{F}) \), if \( \gamma = \frac{1}{2}\alpha + \frac{1}{2}\beta \) and \( \delta = \frac{1}{2}\alpha - \frac{1}{2}\beta \), then \( \gamma + \delta = \alpha \) and \( \gamma - \delta = \beta \).

**Proof.** As we are dealing with a commutative group, we have

\[
\gamma + \delta = \left[\frac{1}{2}\alpha + \frac{1}{2}\beta\right] + \left[\frac{1}{2}\alpha + (-\frac{1}{2}\beta)\right] = \frac{1}{2}\alpha + \frac{1}{2}\alpha + \frac{1}{2}\beta + (-\frac{1}{2}\beta) = \alpha + 0_\mathcal{F} = \alpha.
\]

Similarly

\[
\gamma - \delta = \left[\frac{1}{2}\alpha + \frac{1}{2}\beta\right] - \left[\frac{1}{2}\alpha + (-\frac{1}{2}\beta)\right] = \frac{1}{2}\alpha + \frac{1}{2}\beta - (-\frac{1}{2}\alpha + \frac{1}{2}\beta) = \beta.
\]

### 9.5 THE COSINE AND SINE RULES

#### 9.5.1 The cosine rule

**NOTATION.** Let \( A, B, C \) be non-collinear points. Then for the triangle \( [A, B, C] \) we denote by \( a \) the length of the side which is opposite the vertex \( A \), by \( b \) the length of the side opposite \( B \), and by \( c \) the length of the side opposite \( C \), so that

\[
a = |B, C|, \quad b = |C, A|, \quad c = |A, B|.
\]

We also use the notation

\[
\alpha = \angle BAC, \quad \beta = \angle CBA, \quad \gamma = \angle ACB.
\]

Let \( A, B, C \) be non-collinear points, let \( D = \pi_{BC}(A) \) and write \( x = |B, D| \). Then with the notation above, \( 2ax = a^2 + c^2 - b^2 \) when \( D \in [B, C] \) or \( C \in [B, D] \), while \( 2ax = b^2 - a^2 - c^2 \) when \( B \in [D, C] \).

**Proof.** When \( D \in [B, C] \) we have \( |D, C| = a - x \), and when \( C \in [B, D] \), \( |D, C| = x - a \). In both of these cases, by Pythagoras’ theorem used twice we have

\[
|A, D|^2 = |A, B|^2 - |B, D|^2 = c^2 - x^2, \quad |A, C|^2 - |D, C|^2 = b^2 - (a - x)^2.
\]

On equating these we have \( c^2 - x^2 = b^2 - a^2 + 2ax - x^2 \), giving \( 2ax = c^2 + a^2 - b^2 \).

When \( B \in [D, C] \) we have \( |D, C| = a + x \), so by the formulae for \( |A, D|^2 \) above we have \( c^2 - x = b^2 - (a + x)^2 \). This simplifies to \( 2ax = b^2 - a^2 - c^2 \).
The cosine rule. *In each triangle* \([A, B, C]\),

\[
\cos \alpha = \frac{b^2 + c^2 - a^2}{2bc}, \quad \cos \beta = \frac{c^2 + a^2 - b^2}{2ca}, \quad \cos \gamma = \frac{a^2 + b^2 - c^2}{2ab}.
\]

**Proof** On returning to the last proof, we note that when \(D \in [B, C]\) we have

\[
\cos \beta = \frac{|B, D|}{|B, A|} = \frac{x}{c},
\]

while

\[
x = \frac{c^2 + a^2 - b^2}{2a},
\]

and so

\[
\cos \beta = \frac{c^2 + a^2 - b^2}{2ca}.
\]

Similarly, when \(B \in [D, C]\) we have

\[
\cos \beta = \frac{|B, D|}{|B, A|} = -\frac{x}{c},
\]

while

\[
x = -\frac{c^2 + a^2 - b^2}{2a},
\]

and this gives the same conclusion.

**9.5.2 The sine rule**

The sine rule *In each triangle* \([A, B, C]\),

\[
\frac{\sin \alpha}{a} = \frac{\sin \beta}{b} = \frac{\sin \gamma}{c}.
\]

**Proof.** By the cosine rule

\[
\cos^2 \alpha = 1 - \sin^2 \alpha = \frac{(b^2 + c^2 - a^2)^2}{4a^2b^2c^2},
\]
so that
\[
\frac{\sin^2 \alpha}{a^2} = \frac{4b^2c^2 - (b^2 + c^2 - a^2)^2}{4a^2b^2c^2}
\]
\[
= \frac{2(b^2c^2 + c^2a^2 + a^2b^2) - (a^4 + b^4 + c^4)}{4a^2b^2c^2}.
\]
As the right-hand side here is symmetrical in \(a, b\) and \(c\) we must have
\[
\frac{\sin^2 \alpha}{a^2} = \frac{\sin^2 \beta}{b^2} = \frac{\sin^2 \gamma}{c^2}.
\]
As the sines of wedge-angles are all positive, we may take square roots here and the result follows.

9.5.3

In a triangle \([A, B, C]\), let the mid-line of \(\overline{BAC}\) meet \([B, C]\) at \(D\) and let \(d_1 = |A, D|\). Then

\[
d_1 = \frac{2bc}{b+c} \cos \frac{1}{2} \alpha.
\]

**Proof.** By 5.5

\[
\frac{|B, D|}{|D, C|} = \frac{c}{b},
\]
so that
\[
|B, D| = \frac{c}{b+c} a.
\]
On applying the sine rule to the triangle \([A, B, D]\) we have that

\[
\frac{d_1}{\sin \beta} = \frac{ca}{b+c} \frac{1}{\sin \frac{1}{2} \alpha},
\]
and so

\[
d_1 = \frac{ca \sin \beta}{b+c \sin \frac{1}{2} \alpha} = \frac{ca}{b+c} \frac{b}{\sin \frac{1}{2} \alpha} = \frac{ca}{b+c} \frac{a}{\sin \frac{1}{2} \alpha} = \frac{2bc}{b+c} \cos \frac{1}{2} \alpha.
\]

9.5.4  **The Steiner-Lehmus theorem, 1842**

Suppose that we are given a triangle \([A, B, C]\), that the mid-line of \(\overline{CBA}\) meets \(CA\) at \(E\), that the mid-line of \(\overline{ACB}\) meets \(AB\) at \(F\), and that \(|B, E| = |C, F|\). We then wish to show that the triangle is isosceles. This is known as the Steiner-Lehmus theorem.

![Figure 9.13. Steiner-Lehmus theorem.](image-url)
Proof. By the last result we have \( d_2 = \frac{2ca}{c+a} \cos \frac{1}{2} \beta \), \( d_3 = \frac{2ab}{a+b} \cos \frac{1}{2} \gamma \). Then

\[
d_2^2 - d_3^2 = 4a^2 \left[ \frac{c^2}{(c+a)^2} \cos^2 \frac{1}{2} \beta - \frac{b^2}{(a+b)^2} \cos^2 \frac{1}{2} \gamma \right]
\]

\[
= 2a^2 \left[ \frac{c^2}{(c+a)^2} (1 + \cos \beta) - \frac{b^2}{(a+b)^2} (1 + \cos \gamma) \right]
\]

\[
= 2a^2 \left[ \frac{c^2}{(c+a)^2} \left( 1 + \frac{c^2 + a^2 - b^2}{2ca} \right) - \frac{b^2}{(a+b)^2} \left( 1 + \frac{a^2 + b^2 - c^2}{2ab} \right) \right]
\]

\[
= a \left[ c - b + \frac{bc^2}{(a+b)^2} - \frac{b^2c}{(c+a)^2} \right]
\]

\[
= a \left[ c - b + \frac{bc}{(a+b)^2(c+a)^2} [c(c+a)^2 - b(a+b)^2] \right]
\]

\[
= a(c - b) \left[ 1 + \frac{bc}{(a+b)^2(c+a)^2} [a^2 + b^2 + c^2 + 2ab + bc + 2ca] \right]
\]

Then \( b < c \) implies that \( d_2 > d_3 \).

### 9.6 COSINE AND SINE OF ANGLES EQUAL IN MAGNITUDE

#### 9.6.1

If angles \( \alpha, \beta \) are such that \( |\alpha| \circ = |\beta| \circ \), then \( \cos \alpha = \cos \beta \) and \( \sin \alpha = \sin \beta \). Conversely if \( \cos \alpha = \cos \beta \) and \( \sin \alpha = \sin \beta \), then \( |\alpha| \circ = |\beta| \circ \) unless one of them is null and the other is full.

Proof. Let \( \mathcal{F} = ([O, I], [O, J]) \) and \( \alpha \) have support \( \overline{QOP} \) and indicator in \( \mathcal{H}_1 \), where \( |O, P| = |O, Q| = k \). Let \( \mathcal{F}' = ([O', I'], [O', J']) \) and \( \beta \) have support \( \overline{Q'O'P'} \) and indicator in \( \mathcal{H}'_1 \), where \( |O', P'| = |O', Q'| = k \).
We suppose first that \(|\alpha| = |\beta| \leq 90\) so that \(P \in \mathcal{D}_1, P' \in \mathcal{D}_1\). Then \(U \in [O, Q], V \in [O, R], U' \in [O', Q'], V' \in [O', R']\). The triangles \([O, U, P], [O', U', P']\) are congruent by the ASA-principle, so \(|O, U| = |O', U'|, |O, V| = |O', V'|\). Then \(|Q, U| = |Q', U'\), \(|R, V| = |R', V'|\). Hence \(\cos \alpha = \cos \beta, \sin \alpha = \sin \beta\).

Similar arguments work in the case of the other three quadrants of \(\mathcal{F}\).

Conversely, let \(\cos \alpha = \cos \beta, \sin \alpha = \sin \beta\). Suppose first that \(\cos \alpha \geq 0, \sin \alpha \geq 0\). Then \(P \in \mathcal{D}_1, P' \in \mathcal{D}_1\). But \(|Q, U| = |Q', U'|, |R, V| = |R', V'|\) and so \(|O, U| = |O', U'|, |U, P| = |U', P'|\). By the SSS-principle, the triangles \([O, U, P], [O', U', P']\) are congruent so \(|\alpha| = |\beta|\), unless we have a degeneration from a triangle and one angle is null and the other is full.

A similar argument works for the other three quadrants of \(\mathcal{F}\).

**Exercises**

9.1 Prove that for all angles \(\alpha \in \mathcal{A^*}(\mathcal{F})\),

\[-1 \leq \cos \alpha \leq 1, \quad -1 \leq \sin \alpha \leq 1.\]

9.2 Let \(\mathcal{C}_1\) be the circle with centre \(O\) and radius of length \(k\). Let \(Z_1 \equiv (k \cos \theta, k \sin \theta), Z_2 \equiv (-k, 0), Z_3 \equiv (k, 0)\), so that \(Z_1\) is a point on this circle, and \([Z_2, Z_3]\) is a diameter. Let \(\mathcal{C}_2\) be the circle with \([Z_1, Z_3]\) as diameter. Find the coordinates of the second point in which \(\mathcal{C}_2\) meets the line \(Z_2Z_3\). How does this relate to 4.3.3?

9.3 If \(D\) is the mid-point of the side \([B, C]\) of the triangle \([A, B, C]\) and \(d_1 = |A, D|\), prove that

\[4d_1^2 = b^2 + c^2 + 2bc \cos \alpha.\]

Deduce that \(2d_1 > a\) if and only if \(\alpha\) is an acute angle.

9.4 Prove the identities

\[
\cos \alpha + \cos \beta = 2\cos(\frac{1}{2}\alpha + \frac{1}{2}\beta) \cos(\frac{1}{2}\alpha - \frac{1}{2}\beta),
\]

\[
\cos \alpha - \cos \beta = -2\sin(\frac{1}{2}\alpha + \frac{1}{2}\beta) \sin(\frac{1}{2}\alpha - \frac{1}{2}\beta),
\]

and find similar results for \(\sin \alpha + \sin \beta\) and \(\sin \alpha - \sin \beta\).

9.5 Show that

\[
\sin 270_{\mathcal{F}} + \sin 210_{\mathcal{F}} = -\frac{3}{2},
\]

and yet

\[
2\sin[\frac{1}{2}(270_{\mathcal{F}} + 210_{\mathcal{F}})] \cos[\frac{1}{2}(270_{\mathcal{F}} - 210_{\mathcal{F}})] = \frac{3}{2}.
\]
10

Complex coordinates; sensed angles; angles between lines

COMMENT. In this chapter we utilise complex coordinates, develop sensed angles and rotations, complete our formulae for axial symmetries and identify isometries in terms of translations, rotations and axial symmetries. We go on to establish more results on circles and consider a variant on the angles we have been dealing with.

10.1 COMPLEX COORDINATES

10.1.1

We now introduce the field of complex numbers \((C, +, \cdot)\) as an aid. This has an added convenience when doing coordinate geometry. We recall that any \(z \in C\) can be written uniquely in the form \(z = x + iy\), where \(x, y \in \mathbb{R}\) and \(i^2 = -1\). We use the notations |\(z| = \sqrt{x^2 + y^2}\), \(\bar{z} = x - iy\) for the modulus or absolute value, and complex conjugate, respectively, of \(z\). As well as having the familiar properties for addition, subtraction, multiplication and division (except division by 0), these have the further properties:

\[
\bar{z} = z, \quad \overline{z_1 z_2} = \overline{z_1} \overline{z_2}, \quad \forall z, z_1, z_2 \in C; \quad \bar{z} = z \iff z \in \mathbb{R};
\]

\[
|z_1 z_2| = |z_1| |z_2|, \quad |\bar{z}| = |z|, \quad \forall z, z_1, z_2 \in C; \quad |z| = z \iff z \in \mathbb{R} \text{ and } z \geq 0;
\]

\[
z\bar{z} = |z|^2, \quad \forall z \in C; \quad \frac{1}{z} = \frac{\bar{z}}{|z|^2}, \quad \forall z \neq 0.
\]

**Definition.** Let \(\mathcal{F} = ([O, I], [O, J])\) be a frame of reference for \(\Pi\) and for any point \(Z \in \Pi\) we recall the Cartesian coordinates \((x, y)\) of \(Z\) relative to \(\mathcal{F}\), \(Z \equiv \mathcal{F} (x, y)\). If \(z = x + iy\), we also write \(Z \sim \mathcal{F} z\), and call \(z\) a **Cartesian complex coordinate** of the point \(Z\) relative to \(\mathcal{F}\). When \(\mathcal{F}\) can be understood, we can relax our notation and denote this by \(Z \sim z\).

**Complex coordinates have the following properties:**

(i) \(|z_2 - z_1| = |Z_1, Z_2|\) for all \(Z_1, Z_2\).

Geometry with Trigonometry
http://dx.doi.org/10.1016/B978-0-12-805066-8.50010-0
© 2016 Elsevier Ltd. All rights reserved.
(ii) If \( Z_1 \neq Z_2 \), then \( Z \in Z_1Z_2 \) if and only if \( z - z_1 = t(z_2 - z_1) \) for some \( t \in \mathbb{R} \).

(iii) If \( Z_1 \neq Z_2 \), then \( Z \in [Z_1, Z_2] \) if and only if \( z - z_1 = t(z_2 - z_1) \) for some \( t \geq 0 \).

(iv) If \( Z_1 \neq Z_2 \), then \( Z \in [Z_1, Z_2] \) if and only if \( z - z_1 = t(z_2 - z_1) \) for some \( t \) such that \( 0 \leq t \leq 1 \).

(v) For \( Z_1 \neq Z_2 \) and \( Z_3 \neq Z_4 \), \( Z_1Z_2 \parallel Z_3Z_4 \) if and only if \( z_4 - z_3 = t(z_2 - z_1) \) for some \( t \in \mathbb{R} \setminus \{0\} \).

(vi) For \( Z_1 \neq Z_2 \) and \( Z_3 \neq Z_4 \), \( Z_1Z_2 \perp Z_3Z_4 \) if and only if \( z_4 - z_3 = t(z_2 - z_1) \) for some \( t \in \mathbb{R} \setminus \{0\} \).

**Proof.**

(i) For \( |z_2 - z_1|^2 = |x_2 - x_1 + i(y_2 - y_1)|^2 = (x_2 - x_1)^2 + (y_2 - y_1)^2 = |Z_1Z_2|^2 \).

(ii) For \( z - z_1 = t(z_2 - z_1) \) if and only if \( x - x_1 + i(y - y_1) = t[x_2 - x_1 + i(y_2 - y_1)] \).

If this happens for some \( t \in \mathbb{R} \), then \( x - x_1 = t(x_2 - x_1) \), \( y - y_1 = t(y_2 - y_1) \). By 6.4.1, Corollary (i), this implies that \( Z \in Z_1Z_2 \).

Conversely if \( Z \in Z_1Z_2 \), by the same reference there is such a \( t \in \mathbb{R} \) and it follows that \( z - z_1 = t(z_2 - z_1) \).

(iii) and (iv). In (ii) we have \( Z \in [Z_1, Z_2] \) when \( t \geq 0 \) by 6.4.1, Corollary, and similarly \( Z \in [Z_1, Z_2] \) when \( 0 \leq t \leq 1 \).

(v) By 6.5.1, Corollary (ii), \( Z_1Z_2 \) and \( Z_3Z_4 \) are parallel only if

\[ -(y_2 - y_1)(x_4 - x_3) + (y_4 - y_3)(x_2 - x_1) = 0. \] (10.1.1)

We note that as \( Z_1 \neq Z_2 \) we must have either \( x_1 \neq x_2 \) or \( y_1 \neq y_2 \).

Suppose first that \( z_4 - z_3 = t(z_2 - z_1) \) for some \( t \in \mathbb{R} \). Then

\[ x_4 - x_3 + i(y_4 - y_3) = t(x_2 - x_1) + i(y_2 - y_1), \]

and so as \( t \) is real,

\[ x_4 - x_3 = t(x_2 - x_1), \quad y_4 - y_3 = t(y_2 - y_1). \]

Then

\[ -(y_2 - y_1)(x_4 - x_3) + (y_4 - y_3)(x_2 - x_1) = -(y_2 - y_1)t(x_2 - x_1) + t(y_2 - y_1)(x_2 - x_1) = 0, \]

so that (10.1.1) holds and hence the lines are parallel.

Conversely suppose that the lines are parallel so that (10.1.1) holds. When \( x_1 \neq x_2 \), we let

\[ t = \frac{x_4 - x_3}{x_2 - x_1}, \]

so that \( x_4 - x_3 = t(x_2 - x_1) \). On inserting this in (10.1.1), we have

\[ -t(y_2 - y_1)(x_2 - x_1) + (y_4 - y_3)(x_2 - x_1) = 0, \]
from which we have \( y_4 - y_3 = t(y_2 - y_1) \).

When \( x_2 - x_1 = 0 \), by (10.1.1) we must have \( x_4 - x_3 = 0 \). We now let \( t = \frac{y_4 - y_3}{y_2 - y_1} \), so that \( y_4 - y_3 = t(y_2 - y_1) \). For this \( t \) we also have, trivially, \( x_4 - x_3 = t(x_2 - x_1) \).

Thus in both cases \( x_4 - x_3 = t(x_2 - x_1) \), \( y_4 - y_3 = t(y_2 - y_1) \), and so on combining these

\[
x_4 - x_3 + t(y_4 - y_3) = t(x_2 - x_1) + ut(y_2 - y_1).
\]

Thus \( z_4 - z_3 = t(z_2 - z_1) \).

(vi) By 6.5.1, Corollary (i), these lines are perpendicular if and only if

\[
(y_2 - y_1)(y_4 - y_3) + (x_2 - x_1)(x_4 - x_3) = 0. \tag{10.1.2}
\]

Suppose first that \( z_4 - z_3 = t(t(z_2 - z_1) \) for some \( t \in \mathbb{R} \). Then

\[
x_4 - x_3 + t(y_4 - y_3) = ut(x_2 - x_1) - t(y_2 - y_1),
\]

and so as \( t \) is real, \( x_4 - x_3 = -t(y_2 - y_1) \), \( y_4 - y_3 = t(x_2 - x_1) \). Then

\[
(y_2 - y_1)(y_4 - y_3) + (x_2 - x_1)(x_4 - x_3) = (y_2 - y_1)t(x_2 - x_1) - t(x_2 - x_1)(y_2 - y_1) = 0,
\]

so that (10.1.2) holds, and hence the lines are perpendicular.

Conversely suppose that the lines are perpendicular so that (10.1.2) holds. When \( x_1 \neq x_2 \), we let

\[
t = \frac{y_4 - y_3}{x_2 - x_1}
\]

so that \( y_4 - y_3 = t(x_2 - x_1) \). On inserting this in (10.1.2), we have

\[
(y_2 - y_1)t(x_2 - x_1) + (x_2 - x_1)(x_2 - x_1) = 0,
\]

from which we have \( x_4 - x_3 = -t(y_2 - y_1) \).

When \( x_2 - x_1 = 0 \), by (10.1.2) we must have \( y_4 - y_3 = 0 \). We now let

\[
t = \frac{x_4 - x_3}{y_2 - y_1},
\]

so that \( x_4 - x_3 = -t(y_2 - y_1) \). For this \( t \) we also have, trivially, \( y_4 - y_3 = t(x_2 - x_1) \).

Thus in both cases \( x_4 - x_3 = -t(y_2 - y_1) \), \( y_4 - y_3 = t(x_2 - x_1) \), and so on combining these

\[
x_4 - x_3 + t(y_4 - y_3) = -t(y_2 - y_1) + ut(x_2 - x_1) = ut[x_2 - x_1 + t(y_2 - y_1)].
\]

Thus \( z_4 - z_3 = t(z_2 - z_1) \).
10.2 COMPLEX-VALUED DISTANCE

10.2.1 Complex-valued distance

The material in 7.6 is long established; we can generalise those concepts of sensed distances and sensed ratios as follows.

**Definition.** Let \( \mathcal{F} \) be a frame of reference for \( \Pi \). If \( Z_1 \sim_{\mathcal{F}} z_1, Z_2 \sim_{\mathcal{F}} z_2 \) we define \( \frac{Z_1Z_2_{\mathcal{F}}}{Z_1Z_2_{\mathcal{F}}} = z_2 - z_1 \), and call this a **complex-valued distance** from \( Z_1 \) to \( Z_2 \). We then consider also \( \frac{Z_3Z_4_{\mathcal{F}}}{Z_1Z_2_{\mathcal{F}}} \), a ratio of complex-valued distances or **complex ratio** when \( Z_1 \neq Z_2 \).

We show that this latter reduces to the sensed ratio

\[
\frac{Z_3Z_4_{\mathcal{F}}}{Z_1Z_2_{\mathcal{F}}} = \frac{s_4 - s_3}{s_2 - s_1},
\]

when \( Z_1, Z_2, Z_3, Z_4 \) are points of a line \( l \). As in 7.6.1 we suppose that \( l \) is the line \( W_0W_1 \) where \( W_0 \equiv (u_0, v_0) \) and \( W_1 \equiv (u_1, v_1) \), and has parametric equations

\[
x = u_0 + s(u_1 - u_0), \quad y = v_0 + s(v_1 - v_0).
\]

By 10.1.1(ii) \( l \) then has complex parametric equation \( z = w_0 + s(w_1 - w_0) \). If \( Z_1, Z_2, Z_3, Z_4 \) have parameters \( s_1, s_2, s_3, s_4 \), respectively, then

\[
z_2 - z_1 = (z_2 - w_0) - (z_1 - w_0) = (s_2 - s_1)(w_1 - w_0), \quad z_4 - z_3 = (s_4 - s_3)(w_1 - w_0),
\]

and so

\[
\frac{Z_3Z_4_{\mathcal{F}}}{Z_1Z_2_{\mathcal{F}}} = \frac{s_4 - s_3}{s_2 - s_1}.
\]

By 7.6.1 this is equal to the sensed ratio. This shows that for four collinear points a ratio of complex-valued distances reduces to the corresponding ratio of sensed distances.

**COMMENT.** We could make considerable use of this concept in our notation for the remainder of this chapter but in fact we use it sparingly.

10.2.2 A complex-valued trigonometric function

For \( Z_0 \sim_{\mathcal{F}} z_0 \) and \( \mathcal{F}' = t_{OZ_0}(\mathcal{F}) \), let \( I_0 = t_{OZ_0}(I) \); we recall from 8.3 that \( Z \sim_{\mathcal{F}'} z - z_0 \). Then if \( Z \neq Z_0 \), \( Z \sim_{\mathcal{F}} z \) and \( \theta = \angle_{\mathcal{F}'} I_0Z_0Z \), by 9.2.2 we have

\[
x - x_0 = r\cos \theta, \quad y - y_0 = r\sin \theta,
\]

where \( r = |Z_0, Z| = |z - z_0| \). It follows that \( z - z_0 = r(\cos \theta + i\sin \theta) \).
If \( Z_1 \neq Z_0 \), \( Z_1 \sim \phi z_1 \) and \( \alpha = \angle \phi \mathcal{I}_0 Z_0 Z_1 \), then by this
\[
x_1 - x_0 = k \cos \alpha, \quad y_1 - y_0 = k \sin \alpha,
\]
where \( k = |Z_0 Z_1| \). On inserting this in 6.3.1 Corollary, we see that
\[
Z_0 Z_1 = \{ Z \equiv (x,y) : (x-x_0) \sin \alpha - (y-y_0) \cos \alpha = 0 \}.
\]
When \( Z_0 Z_1 \) is not parallel to \( OJ \) we have that \( \cos \alpha \neq 0 \) and this equation of the line \( Z_0 Z_1 \) can be re-written as \( y - y_0 = \tan \alpha (x - x_0) \) where \( \tan \alpha = \sin \alpha / \cos \alpha \). We call \( \tan \alpha \) the slope of this line.

**Notation.** For any angle \( \theta \) we write \( \text{cis} \theta = \cos \theta + i \sin \theta \).

The complex-valued function \( \text{cis} \) has the properties:

(i) For all \( \theta, \phi \in \mathcal{F} \), \( \text{cis} (\theta + \phi) = \text{cis} \theta \cdot \text{cis} \phi \).

(ii) \( \text{cis} 0 = 1 \).

(iii) For all \( \theta \in \mathcal{F} \), \( \frac{1}{\text{cis} \theta} = \text{cis} (-\theta) \).

(iv) For all \( \theta \in \mathcal{F} \), \( \overline{\text{cis} \theta} = \text{cis} (-\theta) \), where \( \bar{z} \) denotes the complex conjugate of \( z \).

(v) For all \( \theta \), \( |\text{cis} \theta| = 1 \).

**Proof.**

(i) For
\[
\text{cis} \theta \cdot \text{cis} \phi = (\cos \theta + i \sin \theta)(\cos \phi + i \sin \phi)
= \cos \theta \cos \phi - \sin \theta \sin \phi + i[\sin \theta \cos \phi + \cos \theta \sin \phi]
= \cos(\theta + \phi) + i \sin(\theta + \phi) = \text{cis}(\theta + \phi).
\]

(ii) For \( \text{cis} 0 = \cos 0 + i \sin 0 = 1 + i \cdot 0 = 1 \).
Complex coordinates; sensed angles; angles between lines

Ch. 10

(iii) For by (i) and (ii) of the present theorem,
\[ \text{cis } \theta \cdot \text{cis } (-\theta) = \text{cis } (\theta - \theta) = \text{cis } 0 = 1. \]

(iv) For the complex conjugate of \( \cos \theta + i \sin \theta \) is \( \cos \theta - i \sin \theta = \cos (-\theta) + i \sin (-\theta) \).

(v) For \( |\text{cis } \theta|^2 = \cos^2 \theta + \sin^2 \theta = 1 \).

10.3 ROTATIONS AND AXIAL SYMMETRIES

10.3.1 Rotations

Definition. Let \( Z_0 \sim \mathcal{F}, t \) be the translation \( t_{OZ_0}, \mathcal{F}' = t(\mathcal{F}) \) and \( I_0 = t(I) \). Let \( \alpha \in \mathcal{A}(\mathcal{F}') \). The function \( r_{\alpha;Z_0} : \Pi \rightarrow \Pi \) defined by

\[ Z \sim \mathcal{F} z, Z' \sim \mathcal{F}' z', r_{\alpha;Z_0}(Z) = Z' \text{ if } z' - z_0 = (z - z_0)\text{cis } \alpha, \]

is called rotation about the point \( Z_0 \) through the angle \( \alpha \).

If \( r_{\alpha;Z_0}(Z) = Z' \) we have the following properties:

(i) In all cases \( |Z_0, Z'| = |Z_0, Z| \), and hence in particular \( r_{\alpha;Z_0}(Z_0) = Z_0 \).

(ii) If \( Z \neq Z_0 \), \( \theta = \angle \mathcal{F} I_0 Z_0 Z \) and \( \theta' = \angle \mathcal{F}' I_0 Z_0 Z' \), then \( \theta' = \theta + \alpha \).

(iii) If \( Z_0 \sim \mathcal{F} z_0, Z \sim \mathcal{F} z, Z' \sim \mathcal{F}' z', \) then \( r_{\alpha;Z_0} \) has the real coordinates form

\[ x' - x_0 = \cos \alpha (x - x_0) - \sin \alpha (y - y_0), \]
\[ y' - y_0 = \sin \alpha (x - x_0) + \cos \alpha (y - y_0), \]
which has the matrix form

\[
\begin{pmatrix}
  x' - x_0 \\
  y' - y_0 
\end{pmatrix} = \begin{pmatrix}
  \cos \alpha & -\sin \alpha \\
  \sin \alpha & \cos \alpha 
\end{pmatrix}
\begin{pmatrix}
  x - x_0 \\
  y - y_0 
\end{pmatrix}.
\]

**Proof.**

(i) For \(|z' - z_0| = |(z - z_0)\text{cis} \alpha| = |z - z_0|\text{cis} \alpha| = |z - z_0|.

(ii) For by 10.2.2

\[z - z_0 = |z - z_0|\text{cis} \theta, \ z' - z_0 = |z' - z_0|\text{cis} \theta',\]

and so \(|z' - z_0|\text{cis} \theta' = |z - z_0|\text{cis} \theta\text{cis} \alpha\). Hence \(\text{cis} \theta' = \text{cis} \theta\text{cis} \alpha = \text{cis} (\theta + \alpha)\) and so \(\theta' = \theta + \alpha\) by 9.2.2.

(iii) Now 
\[x' - x_0 + i(y' - y_0) = (\cos \alpha + i\sin \alpha)[x - x_0 + i(y - y_0)],\]

and so
\[x' - x_0 = \cos \alpha.(x - x_0) - \sin \alpha.(y - y_0),\]
\[y' - y_0 = \sin \alpha.(x - x_0) + \cos \alpha.(y - y_0).\]

**COMMENT.** The rotation \(r_{\alpha;Z_0}\) is characterised by (i) and (ii), as the steps can be traced backwards. Why a frame of reference \(\mathcal{F}'\) is prominent in this characterisation stems from the need to identify the angles \(\alpha, \theta, \theta'\).

**10.3.2 Formula for an axial symmetry**

![Figure 10.3](image)

The form of equation of a line noted in 10.2.2 can be used in the formula in 6.6.1(iii) for an axial symmetry. However, for practice with complex-valued coordinates we deduce the result independently.
Let \( l \) be the line \( Z_0Z_1, Z_0 \sim \mathcal{F} \ z, \ \mathcal{F}' = t_{OZ_0}(\mathcal{F}), \ I_0 = t_{OZ_0}(I) \) and \( \alpha = \angle \mathcal{F} \ I_0Z_0Z_1. \) Then \( s_1(Z) = Z' \) where

\[
Z \sim \mathcal{F} \ z, \ Z' \sim \mathcal{F} \ z', \ z' - z_0 = (\bar{z} - \bar{z}_0)\cis 2\alpha,
\]

so that \( s_1 \) has the real coordinates form

\[
x' - x_0 = \cos 2\alpha.(x - x_0) + \sin 2\alpha.(y - y_0),
\]

\[
y' - y_0 = \sin 2\alpha.(x - x_0) - \cos 2\alpha.(y - y_0),
\]

and so has the matrix form

\[
\begin{pmatrix}
x' - x_0 \\
y' - y_0
\end{pmatrix} = \begin{pmatrix}
\cos 2\alpha & \sin 2\alpha \\
\sin 2\alpha & -\cos 2\alpha
\end{pmatrix} \begin{pmatrix}
x - x_0 \\
y - y_0
\end{pmatrix}.
\]

**Proof.** To find a formula for \( Z' = s_1(Z) \) we first show that if \( W = \pi_l(Z) \) and \( W \sim \mathcal{F} \) \( w \) then

\[
w - z_0 = \Re \left[ \frac{z - z_0}{z_1 - z_0} \right] (z_1 - z_0), \ z - w = \Im \left[ \frac{z - z_0}{z_1 - z_0} \right] (z_1 - z_0).
\]

To start on this we note that

\[
z - z_0 = \frac{z - z_0}{z_1 - z_0} (z_1 - z_0) = \left[ \Re \left[ \frac{z - z_0}{z_1 - z_0} \right] \right] (z_1 - z_0) + \left[ \Im \left[ \frac{z - z_0}{z_1 - z_0} \right] \right] (z_1 - z_0).
\]

If we now define \( w \) by

\[
w - z_0 = \Re \left[ \frac{z - z_0}{z_1 - z_0} \right] (z_1 - z_0)
\]

then \( W \in Z_0Z_1 \) as \( w - z_0 \) is a real multiple of \( z_1 - z_0. \) But then

\[
z - w = \left[ \Im \left[ \frac{z - z_0}{z_1 - z_0} \right] \right] (z_1 - z_0),
\]

so \( W \) is on a line through \( Z \) which is perpendicular to \( Z_0Z_1. \) Thus \( W \) is the foot of the perpendicular from \( Z \) to \( Z_0Z_1. \)

From this, as \( z' + z = 2w, \) we have \( z' - z = z' - w - (z - w) = -2(z - w) \) so

\[
z' - z = -2t \left[ \Im \left[ \frac{z - z_0}{z_1 - z_0} \right] \right] (z_1 - z_0).
\]

As \( z_1 - z_0 = kcis \alpha \) for some \( k > 0, \) we then have

\[
z' - z = -2t \left[ \frac{\Im \left[ z - z_0 \right]}{kcis \alpha} \right] kcis \alpha = -2t\{ \Im [(z - z_0)\cis (-\alpha)] \} \cis \alpha
\]

\[
= -[(z - z_0)\cis (-\alpha) - (\bar{z} - \bar{z}_0)\cis \alpha] \cis \alpha = -(z - z_0) + (\bar{z} - \bar{z}_0)\cis 2\alpha
\]
and so \( z' - z_0 = (\bar{z} - \bar{z}_0) \text{cis } 2\alpha \). Hence
\[
x' - x_0 + i(y' - y_0) = [x - x_0 - i(y - y_0)](\cos 2\alpha + i \sin 2\alpha),
\]
so that
\[
x' - x_0 = \cos 2\alpha \cdot (x - x_0) + \sin 2\alpha \cdot (y - y_0),
\]
\[
y' - y_0 = \sin 2\alpha \cdot (x - x_0) - \cos 2\alpha \cdot (y - y_0).
\]

We can express this in matrix form as stated.
We denote \( s_1 \) by \( s_{\alpha;Z_0} \) as well.

### 10.4 SENSED ANGLES

#### 10.4.1

**Definition.** For \( F' = t_{O,Z_0}(F) \), let \( I_0 = t_{O,Z_0}(I) \). Then if \( Z_1 \neq Z_0, Z_2 \neq Z_0 \), we let \( \theta_1 = \angle_{\mathcal{F}} I_0 Z_0 Z_1 \) and \( \theta_2 = \angle_{\mathcal{F}} I_0 Z_0 Z_2 \). We define the **sensed-angle** \( \angle_{\mathcal{F}} Z_1 Z_0 Z_2 \) to be \( \theta_2 - \theta_1 \).

**Sensed angles have the following properties.**
Throughout \( Z_0 \sim_{\mathcal{F}} z_0, Z_1 \sim_{\mathcal{F}} z_1, Z_2 \sim_{\mathcal{F}} z_2 \).

(i) **If the points** \( Z_1 \) **and** \( Z_2 \) **are both distinct from** \( Z_0 \), **and** \( \phi \) **is the sensed-angle** \( \angle_{\mathcal{F}} Z_1 Z_0 Z_2 \), **then**
\[
\frac{Z_0 Z_2_{\mathcal{F}}}{Z_0 Z_1_{\mathcal{F}}} = \frac{z_2 - z_0}{z_1 - z_0} = \frac{|Z_0, Z_2|}{|Z_0, Z_1|} \text{cis } \phi.
\]

(ii) **The sensed-angle** \( \angle_{\mathcal{F}} Z_1 Z_0 Z_2 \) **is wedge or reflex according as** \( \Im \frac{z_2 - z_0}{z_1 - z_0} \) **is positive or negative, and this occurs according as** \( \frac{1}{2} [(y_2 - y_0)(x_1 - x_0) - (x_2 - x_0)(y_1 - y_0)] \) **is positive or negative.**
(iii) If the points $Z_1$ and $Z_2$ are both distinct from $Z_0$, then
$$\angle Z_1Z_0Z_2 = -\angle Z_2Z_0Z_1.$$ 

(iv) If $Z_1, Z_2, Z_3$ are all distinct from $Z_0$, then
$$\angle Z_1Z_0Z_2 + \angle Z_2Z_0Z_3 = \angle Z_1Z_0Z_3.$$ 

(v) If $\phi = \angle Z_1Z_0Z_2$, then $r_{\phi,Z_0}([Z_0,Z_1]) = [Z_0,Z_2].$

(vi) In 10.3.1(ii), $\angle ZZ_0Z' = \alpha.$

![Figure 10.5](image-url)

**Proof.** (i) For $z_1 - z_0 = |z_1 - z_0|\text{cis} \theta_1$, $z_2 - z_0 = |z_2 - z_0|\text{cis} \theta_2$ and so
$$\frac{z_2 - z_0}{z_1 - z_0} = \frac{|z_2 - z_0|\text{cis} \theta_2}{|z_1 - z_0|\text{cis} \theta_1} = \frac{|z_2 - z_0|}{|z_1 - z_0|} \text{cis} (\theta_2 - \theta_1).$$
(ii) From (i)
\[
\mathfrak{S} \left[ \frac{z_2 - z_0}{z_1 - z_o} \right] = \frac{|z_2 - z_0|}{|z_1 - z_0|} \sin(\theta_2 - \theta_1),
\]
and this is positive or negative according as \( \theta_2 - \theta_1 \) is wedge or reflex. Moreover
\[
|z_1 - z_0|^2 \mathfrak{S} \left[ \frac{z_2 - z_0}{z_1 - z_0} \right] = \mathfrak{S} \left[ (z_2 - z_0)(z_1 - z_0) \right] = (y_2 - y_0)(x_1 - x_0) - (x_2 - x_0)(y_1 - y_0).
\]

(iii) For the first is \( \theta_2 - \theta_1 \) and the second is \( \theta_1 - \theta_2 \).

(iv) For if \( \theta_1 = \angle_{F} I_0 Z_0 Z_1, \ \theta_2 = \angle_{F} I_0 Z_0 Z_2, \ \theta_3 = \angle_{F} I_0 Z_0 Z_3, \) then
\[
\theta_2 - \theta_1 + (\theta_3 - \theta_2) = \theta_3 - \theta_1.
\]

(v) For if \( Z \in [Z_0, Z_1] \), then \( z = z_0 + t(z_1 - z_0) \) so that \( z_0 + t|z_1 - z_0|\) is wedge or reflex. Moreover
\[
The result follows on expanding the right-hand side here.
\]

(vi) For \( \theta' - \theta = \alpha \).

If the points \( Z_1 \) and \( Z_2 \) are both distinct from \( Z_0 \) and \( \phi = \angle_{F} Z_1 Z_0 Z_2, \) then
\[
|Z_1, Z_2|^2 = |Z_0, Z_1|^2 + |Z_0, Z_2|^2 - 2|Z_0, Z_1||Z_0, Z_2| \cos \phi.
\]

**Proof.** For by (i) in the last result,
\[
z_2 - z_0 = \frac{|Z_0, Z_2|}{|Z_0, Z_1|} (\cos \phi + t \sin \phi)(z_1 - z_0),
\]
so that
\[
z_2 - z_1 = \left[ \frac{|Z_0, Z_2|}{|Z_0, Z_1|} (\cos \phi + t \sin \phi) - 1 \right] (z_1 - z_0).
\]
Then
\[
|Z_1, Z_2|^2 = \left\{ \left[ \frac{|Z_0, Z_2|}{|Z_0, Z_1|} \cos \phi - 1 \right]^2 + \left[ \frac{|Z_0, Z_2|}{|Z_0, Z_1|} \sin \phi \right]^2 \right\} |Z_0, Z_1|^2,
\]
and the result follows on expanding the right-hand side here.

For a non-collinear triple \( (Z_0, Z_1, Z_2) \), let \( \alpha \) be the wedge-angle \( \angle Z_1 Z_0 Z_2 \) and \( \phi \) be the sensed angle \( \angle_{F} Z_1 Z_0 Z_2 \). Then \( \cos \phi = \cos \alpha \) so that \( |\phi| = |\alpha| \) when \( \phi \) is wedge, and \( |\phi| = 360 - |\alpha| \) when \( \phi \) is reflex.

**Proof.** By the last result,
\[
|Z_1, Z_2|^2 = |Z_0, Z_1|^2 + |Z_0, Z_2|^2 - 2|Z_0, Z_1||Z_0, Z_2| \cos \phi,
\]
while by the cosine rule for a triangle in 9.5.1
\[
|Z_1, Z_2|^2 = |Z_0, Z_1|^2 + |Z_0, Z_2|^2 - 2|Z_0, Z_1||Z_0, Z_2| \cos \alpha.
\]
Hence \( \cos \phi = \cos \alpha \) so that \( \sin^2 \phi = \sin^2 \alpha \) and hence \( \sin \phi = \pm \sin \alpha \). The result follows from 9.3.4 and 9.6.
10.5 SENSED-AREA

10.5.1
For points $Z_0 \equiv \mathcal{F} (x_0, y_0)$, $Z_1 \equiv \mathcal{F} (x_1, y_1)$, $Z_2 \equiv \mathcal{F} (x_2, y_2)$ such that $Z_1 \neq Z_0$, $Z_2 \neq Z_0$, and $\theta = \angle \mathcal{F}Z_1Z_0Z_2$ we have

(i) \[ \frac{1}{2} |Z_0, Z_1||Z_0, Z_2| \sin \theta = \frac{1}{2} [(x_1 - x_0)(y_2 - y_0) - (x_2 - x_0)(y_1 - y_0)], \]

(ii) \[ \frac{1}{2} |Z_0, Z_1||Z_0, Z_2| \cos \theta = \frac{1}{2} [(x_1 - x_0)(x_2 - x_0) + (y_1 - y_0)(y_2 - y_0)]. \]

Proof. By 8.3 and 9.2.2, if $k_1 = |Z_0, Z_1|$, $k_2 = |Z_0, Z_2|$, then

\[ x_1 - x_0 = k_1 \cos \theta_1, \quad y_1 - y_0 = k_1 \sin \theta_1, \]
\[ x_2 - x_0 = k_2 \cos \theta_2, \quad y_2 - y_0 = k_2 \sin \theta_2. \]

Then by 9.3.3 and 9.3.4,

\[ k_1 k_2 \sin (\theta_2 - \theta_1) = k_2 \sin \theta_2 k_1 \cos \theta_1 - k_2 \cos \theta_2 k_1 \sin \theta_1 \]
\[ = (y_2 - y_0)(x_1 - x_0) - (x_2 - x_0)(y_1 - y_0). \]

Similarly

\[ k_1 k_2 \cos (\theta_2 - \theta_1) = k_2 \cos \theta_2 k_1 \cos \theta_1 + k_2 \sin \theta_2 k_1 \sin \theta_1 \]
\[ = (x_2 - x_0)(x_1 - x_0) + (y_2 - y_0)(y_1 - y_0). \]

10.5.2 Sensed-area of a triangle

For an ordered triple of points $(Z_1, Z_2, Z_3)$ of points and a frame of reference $\mathcal{F}$, if $Z_1 \equiv \mathcal{F} (x_1, y_1)$, $Z_2 \equiv \mathcal{F} (x_2, y_2)$ and $Z_3 \equiv \mathcal{F} (x_3, y_3)$, we recall from 6.6.2 and 10.5.1(i) $\delta \mathcal{F}(Z_1, Z_2, Z_3)$ defined by the formula

\[ \delta \mathcal{F}(Z_1, Z_2, Z_3) = \frac{1}{2} [x_1(y_2 - y_3) - y_1(x_2 - x_3) + x_2y_3 - x_3y_2] \]
\[ = \frac{1}{2} [(x_2 - x_1)(y_3 - y_1) - (x_3 - x_1)(y_2 - y_1)] \]
\[ = \frac{1}{2} \det \begin{pmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{pmatrix}. \]

By 6.6.2, when $Z_1, Z_2, Z_3$ are non-collinear $|\delta \mathcal{F}(Z_1, Z_2, Z_3)|$ is equal to the area of the triangle $[Z_1, Z_2, Z_3]$. In this case we refer to $\delta \mathcal{F}(Z_1, Z_2, Z_3)$ as the sensed-area of the triangle $[Z_1, Z_2, Z_3]$, with the order of vertices $(Z_1, Z_2, Z_3)$. This was first introduced by Möbius in 1827.
Note that
\[
\delta_\mathcal{A}(Z_1, Z_2, Z_3) = \delta_\mathcal{A}(Z_2, Z_3, Z_1) = \delta_\mathcal{A}(Z_3, Z_1, Z_2)
\]
\[
= -\delta_\mathcal{A}(Z_1, Z_3, Z_2) = -\delta_\mathcal{A}(Z_2, Z_1, Z_3) = -\delta_\mathcal{A}(Z_3, Z_2, Z_1),
\]
so that its value is unchanged if $Z_1, Z_2, Z_3$ are permuted cyclically, and its value is multiplied by $-1$ if the order of these is changed.

We note also that 10.4.1(ii) can be restated as that the sensed-angle \( \angle_{\mathcal{A}} Z_1 Z_0 Z_2 \) is wedge or reflex according as
\[
\Im \frac{z_2 - z_0}{z_1 - z_0} = \Im \frac{Z_0 Z_2 \mathcal{A}}{Z_0 Z_1 \mathcal{A}}
\]
is positive or negative, and this occurs according as \( \delta_\mathcal{A}(Z_0, Z_1, Z_2) \) is positive or negative.

### 10.5.3 A basic feature of sensed-area

A basic feature of sensed-area is given by the following. Let the points $Z_3 \equiv (x_3, y_3)$, $Z_4 \equiv (x_4, y_4)$, $Z_5 \equiv (x_5, y_5)$ be such that
\[
x_3 = (1 - s)x_4 + sx_5, \quad y_3 = (1 - s)y_4 + sy_5,
\]
for some $s \in \mathbb{R}$. Then for all $Z_1, Z_2$,
\[
\delta_\mathcal{A}(Z_1, Z_2, Z_3) = (1 - s)\delta_\mathcal{A}(Z_1, Z_2, Z_4) + s\delta_\mathcal{A}(Z_1, Z_2, Z_5).
\]

For
\[
\delta_\mathcal{A}(Z_1, Z_2, Z_3) = \frac{1}{2} \det \begin{pmatrix}
x_1 & y_1 & 1 \\
x_2 & y_2 & 1 \\
(1 - s)x_4 + sx_5 & (1 - s)y_4 + sy_5 & (1 - s) + s
\end{pmatrix}
\]
\[
= \frac{1}{2} \det \begin{pmatrix}
x_1 & y_1 & 1 \\
x_2 & y_2 & 1 \\
(1 - s)x_4 & (1 - s)y_4 & 1 - s
\end{pmatrix} + \frac{1}{2} \det \begin{pmatrix}
x_1 & y_1 & 1 \\
x_2 & y_2 & 1 \\
sx_5 & sy_5 & s
\end{pmatrix}
\]
\[
= \frac{1}{2}(1 - s) \det \begin{pmatrix}
x_1 & y_1 & 1 \\
x_2 & y_2 & 1 \\
x_4 & y_4 & 1
\end{pmatrix} + \frac{1}{2}s \det \begin{pmatrix}
x_1 & y_1 & 1 \\
x_2 & y_2 & 1 \\
x_5 & y_5 & 1
\end{pmatrix}
\]
\[
= (1 - s)\delta_\mathcal{A}(Z_1, Z_2, Z_4) + s\delta_\mathcal{A}(Z_1, Z_2, Z_5).
\]

### 10.5.4 An identity for sensed-area

An identity that we have for sensed-area is that for any points $Z_1, Z_2, Z_3, Z_4$,
\[
\delta_\mathcal{A}(Z_4, Z_2, Z_3) + \delta_\mathcal{A}(Z_4, Z_3, Z_1) + \delta_\mathcal{A}(Z_4, Z_1, Z_2) = \delta_\mathcal{A}(Z_1, Z_2, Z_3).
\]
For the left-hand side here is equal to

\[
\frac{1}{2} \det \begin{pmatrix} x_4 & y_4 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{pmatrix} + \frac{1}{2} \det \begin{pmatrix} x_4 & y_4 & 1 \\ x_3 & y_3 & 1 \\ x_1 & y_1 & 1 \end{pmatrix} + \frac{1}{2} \det \begin{pmatrix} x_4 & y_4 & 1 \\ x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \end{pmatrix}
\]

\[
= \frac{1}{2} \det \begin{pmatrix} x_4 & y_4 & 1 \\ x_2 - x_1 & y_2 - y_1 & 0 \\ x_3 & y_3 & 1 \end{pmatrix} - \frac{1}{2} \det \begin{pmatrix} x_4 & y_4 & 1 \\ x_3 & y_3 & 1 \\ x_2 - x_1 & y_2 - y_1 & 0 \end{pmatrix} + \frac{1}{2} \det \begin{pmatrix} x_4 & y_4 & 1 \\ x_1 & y_1 & 1 \\ x_2 - x_1 & y_2 - y_1 & 0 \end{pmatrix}
\]

\[
= \frac{1}{2} \det \begin{pmatrix} x_4 & y_4 & 1 \\ x_2 - x_1 & y_2 - y_1 & 0 \\ x_3 & y_3 & 1 \end{pmatrix} - \frac{1}{2} \det \begin{pmatrix} x_4 & y_4 & 1 \\ x_2 - x_1 & y_2 - y_1 & 0 \\ x_1 & y_1 & 1 \end{pmatrix}
\]

\[
= \frac{1}{2} \det \begin{pmatrix} x_4 & y_4 & 1 \\ x_2 - x_1 & y_2 - y_1 & 0 \\ x_3 - x_1 & y_3 - y_1 & 0 \end{pmatrix} = \frac{1}{2} \det \begin{pmatrix} x_1 & y_1 & 1 \\ x_2 - x_1 & y_2 - y_1 & 0 \\ x_3 - x_1 & y_3 - y_1 & 0 \end{pmatrix}
\]

and this is equal to the right-hand side. This was first proved by Möbius.

### 10.6 ISOMETRIES AS COMPOSITIONS

#### 10.6.1

![Diagram](image)
Let $\mathcal{F} = (O, I, O, J)$ and $\mathcal{F}_1 = (Z_0, Z_1, Z_0, Z_2)$ be frames of reference. Let $t_{OZ_0}(I) = I_0$, $t_{OZ_0}(J) = J_0$, $\mathcal{F}' = (Z_0, I_0, Z_0, J_0)$ and $\alpha = \angle \mathcal{F} \mathcal{F}' Z_0 Z_1 Z_2$. Then there is a unique isometry $g$ such that

$$g([O, I]) = [Z_0, Z_1], \quad g([O, J]) = [Z_0, Z_2].$$

When $\angle \mathcal{F} Z_1 Z_0 Z_2$ is a wedge-angle and so is a right-angle $90^\circ$, $\mathcal{F}$, $g = r_{\alpha; Z_0} \circ t_{O, Z_0}$.

When $\angle \mathcal{F} Z_1 Z_0 Z_2$ is a reflex-angle $270^\circ$, and so its co-supported angle is a right-angle,

$$g = s_{\frac{1}{2} \alpha; Z_0} \circ t_{O, Z_0}.$$

**Proof.** Without loss of generality we take $|O, I| = |O, J| = |Z_0, Z_1| = |Z_0, Z_2| = 1$. Let $Z_0 \sim \mathcal{F} z_0, Z_1 \sim \mathcal{F} z_1, Z_2 \sim \mathcal{F} z_2$ and note that $I \sim \mathcal{F} t, z_1 - z_0 = \text{cis} \alpha$. As $Z_0 Z_1 \perp Z_0 Z_2$, by 10.1.1(vi) we have

$$z_2 - z_0 = t(z_1 - z_0) \quad \text{when} \quad \angle \mathcal{F} Z_1 Z_0 Z_2 \quad \text{is a wedge-angle}, \quad (10.6.1)$$

and

$$z_2 - z_0 = -t(z_1 - z_0) \quad \text{when} \quad \angle \mathcal{F} Z_1 Z_0 Z_2 \quad \text{is a reflex-angle}. \quad (10.6.2)$$

In case (10.6.1) we take the transformation $Z' = g(Z)$ where

$$z' = z_0 + z \text{cis} \alpha = z_0 + (z + z_0 - z_0) \text{cis} \alpha.$$

Then for $z = t \geq 0$, $z' = z_0 + t(z_1 - z_0)$ so $g([O, I]) = [Z_0, Z_1].$ Similarly for $z = u (t \geq 0)$, $z' = z_0 + t(z_2 - z_0)$ so $g([O, J]) = [Z_0, Z_2].$

In case (10.6.2) we take the transformation $Z' = g(Z)$ where

$$z' = z_0 + z \text{cis} \alpha = z_0 + (z + z_0 - z_0) \text{cis} \alpha.$$

Then for $z = t \geq 0$, $z' = z_0 + t(z_1 - z_0)$ so $g([O, I]) = [Z_0, Z_1].$ Similarly for $z = u (t \geq 0)$, $z' = z_0 + t(z_2 - z_0)$ so $g([O, J]) = [Z_0, Z_2].$

This establishes the existence of $g$. As to uniqueness, suppose that $f$ is also an isometry such that $f(\mathcal{F}) = \mathcal{F}_1$. Then by 8.2.1(xii), if $Z \sim \mathcal{F} z$ we have $f(Z) \sim \mathcal{F}_1 z$, $g(Z) \sim \mathcal{F}_1 z$, and so $f(Z) = g(Z)$ for all $Z \in \Pi$.

**Corollary.** Let $f$ be any isometry. Then $f$ can be expressed in one or other of the forms

(a) $f = r_{\alpha; Z_0} \circ t_{O, Z_0}$, \hspace{0.5cm} (b) $f = s_{\frac{1}{2} \alpha; Z_0} \circ t_{O, Z_0}$.

**Proof.** In the theorem, take $Z_0 = f(O), Z_1 = f(I), Z_2 = f(J)$ and consequently $f$ is equal to the function $g$ as defined in the proof.
10.7 ORIENTATION OF A TRIPLE OF NON-COLLINEAR POINTS

10.7.1 Definition

We say that an ordered triple \((Z_0, Z_1, Z_2)\) of non-collinear points is **positively or negatively oriented** with respect to \(F\) according as the sensed angle \(\angle_{F} Z_1 Z_0 Z_2\) is wedge or reflex. By 10.4.1(ii) this occurs according as \(\delta_{F}(Z_0, Z_1, Z_2)\) is positive or negative.

**Definition.** Let \(F = (O, I, J)\) and \(F_1 = ([O, Z_1, Z_2])\) be frames of reference. We say that \(F_1\) is **positively or negatively oriented** with respect to \(F\) according as \((Z_0, Z_1, Z_2)\) is positively or negatively oriented with respect to \(F\).

The special isometries have the following effects on orientation:-

(i) Each translation preserves the orientations with respect to \(F\) of all non-collinear triples.

(ii) Each rotation preserves the orientations with respect to \(F\) of all non-collinear triples.

(iii) Each axial symmetry reverses the orientations with respect to \(F\) of all non-collinear triples.

**Proof.**

(i) Let \(f = t_{Z_0, Z_1}\) and \(Z_2 \sim_{F} Z_2, Z_3 \sim_{F} Z_3, Z_4 \sim_{F} Z_4\). Then

\[
z_3' = z_3 + (z_1 - z_0), \quad z_2' = z_2 + (z_1 - z_0),
\]

so that \(z_3' - z_2' = z_3 - z_2\), and similarly \(z_4' - z_2' = z_4 - z_2\). Hence

\[
\frac{z_4' - z_2'}{z_3' - z_2'} = \frac{z_4 - z_2}{z_3 - z_2},
\]

and so by 10.4.1(ii) the result follows.

(ii) Let \(f = r_{\alpha; Z_0}\). Then by 10.3.1

\[
z_2' - z_0 = (\bar{z}_2 - z_0) \text{cis } \alpha, \quad z_3' - z_0 = (\bar{z}_3 - z_0) \text{cis } \alpha,
\]

and so

\[
z_3' - z_2' = (z_3 - z_2) \text{cis } \alpha, \quad z_4' - z_2' = (z_4 - z_2) \text{cis } \alpha.
\]

Hence

\[
\frac{z_4' - z_2'}{z_3' - z_2'} = \frac{z_4 - z_2}{z_3 - z_2},
\]

and so by 10.4.1(ii) the result follows.

(iii) Let \(f = s_{\alpha; Z_0}\). Then by 10.3.2

\[
z_2' - z_0 = (\bar{z}_2 - z_0) \text{cis } 2\alpha, \quad z_3' - z_0 = (\bar{z}_3 - z_0) \text{cis } 2\alpha,
\]
and so
\[ z'_3 - z'_2 = (\bar{z}_3 - \bar{z}_2) \text{cis} 2\alpha, \quad z'_4 - z'_2 = (\bar{z}_4 - \bar{z}_2) \text{cis} 2\alpha. \]

Hence
\[ \frac{z'_4 - z'_2}{z'_3 - z'_2} = \frac{z_4 - z_2}{z_3 - z_2}, \]
so that
\[ \Im \frac{z'_4 - z'_2}{z'_3 - z'_2} = -\Im \frac{z_4 - z_2}{z_3 - z_2}, \]
and so by 10.4.1(ii) the result follows.

Let \( \mathcal{F}, \mathcal{F}_1 \) be frames of reference and \( Z_3, Z_4, Z_5 \) non-collinear points. Let \( \theta = \angle Z_4Z_5Z_3 \) and \( \phi = \angle Z_4Z_5Z_3Z_5 \). Then \( |\phi|^\circ \) is equal to \( |\theta|^\circ \) or \( 360 - |\theta|^\circ \), according as \( \mathcal{F}_1 \) is positively or negatively oriented with respect to \( \mathcal{F} \).

**Proof.** We use the notation of 10.6.1. When \( \mathcal{F}_1 \) is positively oriented with respect to \( \mathcal{F} \), we recall that for \( f(Z) = Z' \) with \( z' = z_0 + z \text{cis} \alpha \), we have \( f(\mathcal{F}) = \mathcal{F}_1 \). On solving this for \( z \) and then interchanging \( z \) and \( z' \), we see that
\[ f^{-1}(Z) \sim \mathcal{F} (z - z_0) \text{cis} (-\alpha). \]

Then by 8.2.1(xii), \( Z = f(f^{-1}(Z)) \sim \mathcal{F}_1 (z - z_0) \text{cis} (-\alpha). \)

Letting \( Z_j \sim \mathcal{F} z_j, Z'_j \sim \mathcal{F}_1 z'_j \) we then have \( z'_j = (z_j - z_0) \text{cis} (-\alpha) \). Thus
\[ \frac{z'_j - z'_3}{z'_4 - z'_3} = \frac{(z_5 - z_0) \text{cis} (-\alpha) - (z_3 - z_0) \text{cis} (-\alpha)}{(z_4 - z_0) \text{cis} (-\alpha) - (z_3 - z_0) \text{cis} (-\alpha)} = \frac{z_5 - z_3}{z_4 - z_3}. \]

But by 10.4.1(i),
\[ \frac{z_5 - z_3}{z_4 - z_3} = \frac{|Z_3, Z_5|}{|Z_3, Z_4|} \text{cis} \theta, \quad \frac{z'_j - z'_3}{z'_4 - z'_3} = \frac{|Z_3, Z_5|}{|Z_3, Z_4|} \text{cis} \phi. \]

Thus \( \text{cis} \phi = \text{cis} \theta \) and so \( |\phi|^\circ = |\theta|^\circ \).

When \( \mathcal{F}_1 \) is negatively oriented with respect to \( \mathcal{F} \), we take instead \( f(Z) = Z' \) with \( z' = z_0 + \bar{z} \text{cis} \alpha \). Now \( f^{-1}(Z) \sim \mathcal{F} (\bar{z} - \bar{z}_0) \text{cis} \alpha \) and so
\[ \frac{z'_j - z'_3}{z'_4 - z'_3} = \frac{(\bar{z}_5 - \bar{z}_0) \text{cis} (\alpha) - (\bar{z}_3 - \bar{z}_0) \text{cis} (\alpha)}{(\bar{z}_4 - \bar{z}_0) \text{cis} (\alpha) - (\bar{z}_3 - \bar{z}_0) \text{cis} (\alpha)} = \frac{\bar{z}_5 - \bar{z}_3}{\bar{z}_4 - \bar{z}_3}. \]

Thus \( \text{cis} \phi = \overline{\text{cis} \theta} = \text{cis} (-\theta) \) and so \( |\phi|^\circ = |(\theta)|^\circ = 360 - |\theta|^\circ \).

Let \( \mathcal{F} \) and \( \mathcal{F}_1 \) be frames of reference. Then the ratios of complex-valued distances
\[ \rho = \frac{Z_3Z_4}{Z_1Z_2}, \quad \sigma = \frac{Z_5Z_4}{Z_1Z_2}, \]
defined in 10.2.1, satisfy \( \sigma = \rho \) when \( \mathcal{F}_1 \) is positively oriented with respect to \( \mathcal{F} \), and \( \sigma = \bar{\rho} \) when \( \mathcal{F}_1 \) is negatively oriented with respect to \( \mathcal{F} \).
Proof We use the notation of 10.6.1. In the case (10.6.1) \( z' = z_0 + z \text{cis} \alpha \) so that
\[
\sigma = \frac{z_4' - z_3'}{z_2' - z_1'} = \frac{(z_4 - z_3) \text{cis} \alpha}{(z_2 - z_1) \text{cis} \alpha} = \rho.
\]
In the case (10.6.2) \( z' = z_0 + \bar{z} \text{cis} \alpha \) so that
\[
\sigma = \frac{z_4' - z_3'}{z_2' - z_1'} = \frac{\bar{z}_4 - \bar{z}_3 \text{cis} \alpha}{\bar{z}_2 - \bar{z}_1 \text{cis} \alpha} = \bar{\rho}.
\]

10.8 SENSED ANGLES OF TRIANGLES, 
THE SINE RULE

10.8.1

Definition. For any non-full angle \( \theta \), we denote by \( \theta_\mathcal{F} \) the angle in \( \mathcal{A}(\mathcal{F}) \) such that \( |\theta_\mathcal{F}| = |\theta| \).

NOTATION. For non-collinear points \( Z_1, Z_2, Z_3 \), we use as standard notation
\[
|Z_2, Z_3| = a, \quad |Z_3, Z_1| = b, \quad |Z_1, Z_2| = c,
\]
\[
u = \frac{b}{c}, \quad \nu = \frac{c}{a}, \quad w = \frac{a}{b},
\]
\[\alpha = \angle_\mathcal{F} Z_2 Z_1 Z_3, \quad \beta = \angle_\mathcal{F} Z_3 Z_2 Z_1, \quad \gamma = \angle_\mathcal{F} Z_1 Z_3 Z_2.
\]
Note that by comparison with 9.5.1 we are now using sensed-angles instead of wedge-angles.
For non-collinear points \(Z_1,Z_2,Z_3\) if
\[
\alpha = \angle_{Z_2}Z_1Z_3, \quad \beta = \angle_{Z_3}Z_2Z_1, \quad \gamma = \angle_{Z_1}Z_3Z_2,
\]
and \(\theta = \alpha_{Z}, \phi = \beta_{Z}, \psi = \gamma_{Z}\), then \(\theta + \phi + \psi = 180_{Z}\).

**Proof.** For
\[
\frac{z_3 - z_1}{z_2 - z_1} = \frac{b}{c} \cdot \text{cis} \theta, \quad \frac{z_1 - z_2}{z_3 - z_2} = \frac{c}{a} \cdot \text{cis} \phi, \quad \frac{z_2 - z_3}{z_1 - z_3} = \frac{a}{b} \cdot \text{cis} \psi.
\]
On multiplying these together, we find that
\[
-1 = \text{cis} \theta \cdot \text{cis} \phi \cdot \text{cis} \psi = \text{cis} (\theta + \phi + \psi).
\]
As \(\text{cis} 180_{Z} = -1\) it follows that \(\theta + \phi + \psi = 180_{Z}\).

With the above notation, the lengths of the sides and the sensed-angles of a triangle \([Z_1,Z_2,Z_3]\) have the properties:

(i) In each case
\[
\frac{c}{a} = \frac{\sin \alpha}{\sin \beta} = \frac{1}{1 - u \text{cis} \alpha},
\]
and two pairs of similar identities obtained from these on advancing cyclically through \((u,v,w)\) and \((\alpha,\beta,\gamma)\).

(ii) In each case
\[
c = b \cos \alpha + a \cos \beta, \quad \frac{\sin \alpha}{a} = \frac{\sin \beta}{b},
\]
and two pairs of similar identities obtained from these on advancing cyclically through \((a,b,c)\) and \((\alpha,\beta,\gamma)\).

**Proof.**

(i) For \(z_3 - z_1 = ucis \alpha (z_2 - z_1)\) so that \(z_3 - z_2 = (1 - ucis \alpha)(z_1 - z_2)\), while \(z_1 - z_2 = vcis \beta (z_3 - z_2)\), which give \((1 - ucis \alpha)vcis \beta = 1\).

(ii) From (i)
\[
1 - u[\cos \alpha + i \sin \alpha] = \frac{1}{v}[\cos \beta - i \sin \beta],
\]
so equating real parts gives \(c = b \cos \alpha + a \cos \beta\), while equating imaginary parts gives \(\sin \alpha/a = \sin \beta/b\).

This result re-derives the sine rule for a triangle.

*If* \(Z_1,Z_2,Z_3\) *are distinct points, then*
\[
\frac{Z_3Z_1_{Z}}{Z_3Z_2_{Z}} + \frac{Z_2Z_1_{Z}}{Z_2Z_3_{Z}} = 1.
\]

**Proof.** For
\[
\frac{z_1 - z_3}{z_2 - z_3} + \frac{z_1 - z_2}{z_3 - z_2} = 1.
\]
10.9 SOME RESULTS ON CIRCLES

10.9.1 A necessary condition to lie on a circle

In this section we provide some results on circles which are conveniently proved using complex coordinates.

Let $Z_1, Z_2$ be fixed distinct points, and $Z$ a variable point, all on the circle $\mathcal{C}(Z_0; k)$.

Let $F' = t_{OZ_0}(F)$ and $\alpha = \angle I_0 Z_0 Z_1$, $\beta = \angle I_0 Z_0 Z_2$, and $\gamma = \frac{1}{2}(\beta - \alpha)$. As $Z$ varies on the circle, in one of the open half-planes with edge $Z_1Z_2$ the sensed angle $\angle FZ_1ZZ_2$ is equal in measure to $\gamma$, while in the other open half-plane with edge $Z_1Z_2$ it is equal in measure to $\gamma + 180^\circ$. Note that $2\gamma = \angle Z_1 Z_0 Z_2$.

**Proof.** Now $z_1 - z_0 = k \text{cis} \alpha$, $z_2 - z_0 = k \text{cis} \beta$ and if $\theta = \angle I_0 Z_0 Z$, then $z - z_0 = k \text{cis} \theta$. We write $\phi = \angle Z_1 ZZ_2$ so that

$$\frac{z_2 - z}{z_1 - z} = l \text{cis} \phi,$$

where $l = \frac{|Z, Z_2|}{|Z, Z_1|}$.

Then

$$l \text{cis} \phi = \frac{\text{cis} \beta - \text{cis} \theta}{\text{cis} \alpha - \text{cis} \theta},$$

while on taking complex conjugates here

$$l \text{cis} (-\phi) = \frac{\text{cis} (-\beta) - \text{cis} (-\theta)}{\text{cis} (-\alpha) - \text{cis} (-\theta)} = \frac{\text{cis} \alpha \text{cis} \theta - \text{cis} \beta}{\text{cis} \beta \text{cis} \theta - \text{cis} \alpha}.$$

By division

$$\text{cis} 2\phi = \frac{\text{cis} \beta}{\text{cis} \alpha} = \text{cis} (\beta - \alpha).$$

Thus $2(\text{cis} \phi)^2 = (\text{cis} \gamma)^2$ so that $\text{cis} \phi = \pm \text{cis} \gamma$. Thus either $\text{cis} \phi = \text{cis} \gamma$ or $\text{cis} \phi = \text{cis} (\gamma + 180^\circ)$, and accordingly

$$\Im \frac{z_2 - z}{z_1 - z} = l \sin \gamma \text{ or } \Im \frac{z_2 - z}{z_1 - z} = l \sin(\gamma + 180^\circ).$$

As $\sin \gamma > 0$, the first of these occurs when $Z$ is in the half-plane with edge $Z_1Z_2$ in which $\Im \frac{z_2 - z}{z_1 - z} > 0$, and the second when $Z$ is in the half-plane with edge $Z_1Z_2$ in which $\Im \frac{z_2 - z}{z_1 - z} < 0$. 

Figure 10.8.
10.9.2 A sufficient condition to lie on a circle

Let $Z_1, Z_2$ be fixed distinct points and $Z$ a variable point. As $Z$ varies in one of the half-planes with edge $Z_1Z_2$, for the sensed angle $\theta = \angle Z_1ZZ_2$ let $|\theta^\circ| = |\gamma^\circ|$ where $\gamma$ is a fixed non-null and non-straight angle in $\mathcal{A}(\mathcal{F})$, while as $Z$ varies in the other half-plane with edge $Z_1Z_2$, let $|\theta^\circ| = |\gamma + 180^\circ|$. Then $Z$ lies on a circle which passes through $Z_1$ and $Z_2$.

**Proof.** We have

$$\frac{z_2 - z}{z_1 - z} = t \text{cis} \gamma$$

for some $t \in \mathbb{R} \setminus \{0\}$. Then

$$z = \frac{z_2 - tz_1 \text{cis} \gamma}{1 - t \text{cis} \gamma}$$

so that with $\cot \gamma = \cos \gamma / \sin \gamma$,

$$z = \frac{1}{2}(z_1 + z_2) - \frac{1}{2}t \cot \gamma (z_2 - z_1)$$

$$= \frac{z_2 - tz_1 \text{cis} \gamma}{1 - t \text{cis} \gamma} - \frac{1}{2}(z_1 + z_2) - \frac{1}{2}t \cot \gamma (z_2 - z_1)$$

$$= \frac{\frac{1}{2}(z_2 - z_1)[1 + t \text{cis} \gamma - t \cot \gamma (1 - t \text{cis} \gamma)]}{1 - t \text{cis} \gamma}$$

$$= \frac{\frac{1}{2}(z_2 - z_1)[\sin \gamma(1 + t \text{cis} \gamma) - t \cos \gamma (1 - t \text{cis} \gamma)]}{\sin \gamma(1 - t \text{cis} \gamma)}$$

and this has absolute value

$$\frac{|z_2 - z_1|}{2|\sin \gamma|}.$$ 

This shows that $Z$ lies on a circle, the centre and length of radius of which are evident.

10.9.3 Complex cross-ratio

Let $Z_2, Z_3, Z_4$ be non-collinear points and $\mathcal{C}$ the circle that contains them. Then $Z \notin Z_3Z_4$ lies in $\mathcal{C}$ if and only if

$$\Im \left( \frac{(z - z_3)(z_2 - z_4)}{(z - z_4)(z_2 - z_3)} \right) = 0.$$
When this holds and $Z$ and $Z_2$ are on the same side of $Z_3 Z_4$, then

$$\frac{(z - z_3)(z_2 - z_4)}{(z - z_4)(z_2 - z_3)} > 0.$$  

**Proof.** The given condition is equivalent to

$$\frac{z - z_4}{z - z_3} = t \frac{z_2 - z_4}{z_2 - z_3}, \quad (10.9.1)$$

for some $t \neq 0$ in $\mathbb{R}$. Let $G_1, G_2$ be the open half-planes with common edge $Z_3 Z_4$, with $Z_2 \in G_1$. Let $\theta = \angle Z_3 Z_2 Z_4$ and $\phi = \angle Z_3 Z_4$. 

Suppose first that (10.9.1) holds. For $Z \in G_1$,

$$\Im \frac{z - z_4}{z - z_3} \text{ and } \Im \frac{z_2 - z_4}{z_2 - z_3}$$

must have the same sign and so $t > 0$; it follows that $\phi = \theta$. For $Z \in G_2$,

$$\Im \frac{z - z_4}{z - z_3} \text{ and } \Im \frac{z_2 - z_4}{z_2 - z_3}$$

must have opposite signs and so $t < 0$; it follows that $\phi = \theta + 180^\circ$. By 10.9.2 $Z \in C$ in both cases.

Conversely let $Z \in C$. Then by (10.9.1) for $Z \in G_1$ we have $\phi = \theta$, while for $Z \in G_2$ we have $\phi = \theta + 180^\circ$, and the result now follows.

The expression $\frac{(z - z_3)(z_2 - z_4)}{(z - z_4)(z_2 - z_3)}$ is called the **cross-ratio** of the ordered set of points $(Z, Z_2, Z_3, Z_4)$.

**10.9.4 Ptolemy’s theorem, c. 200A.D.**

Let $Z_2, Z_3, Z_4$ be non-collinear points and $C$ the circle that contains them. Let $Z \in C$ be such that $Z$ and $Z_3$ are on opposite sides of $Z_2 Z_4$. Then $|Z, Z_4||Z_2, Z_3| + |Z, Z_2||Z_3, Z_4| = |Z, Z_3||Z_2, Z_4|$.

**Proof.** By multiplying out, it can be checked that

$$(z - z_4)(z_2 - z_3) + (z - z_2)(z_3 - z_4) = (z - z_3)(z_2 - z_4).$$
This is an identity due to Euler and from it

\[
\frac{(z - z_4)(z_2 - z_3)}{(z - z_3)(z_2 - z_4)} + \frac{(z - z_2)(z_4 - z_3)}{(z - z_3)(z_4 - z_2)} = 1. \tag{10.9.2}
\]

By 10.9.3 both fractions on the left are real-valued. As \(Z\) and \(Z_3\) are on opposite sides of \(Z_2Z_4\), there is a point \(W\) of \([Z, Z_3]\) on \(Z_2Z_4\). Then \(W\) is an interior point of the circle, and so \(W \in [Z_2, Z_4]\) as the only points of the line \(Z_2Z_4\) which are interior to the circle are in this segment. It follows that \(Z_2\) and \(Z_4\) are on opposite sides of \(Z_2Z_3\). Then \([Z, Z_2], [Z_3, Z_4]\) are in different closed half-planes with common edge the line \(Z_2Z_3\), so they have no points in common. It follows that \(Z\) and \(Z_2\) are on the one side of \(Z_3Z_4\) so the first of the fractions in (10.9.2) is positive, and so equal to its own absolute value. But \([Z, Z_4]\) and \([Z_3, Z_2]\) are in different closed half-planes with common edge \(Z_2Z_3\) so they have no point in common. It follows that \(Z\) and \(Z_4\) are on the one side of \(Z_2Z_3\), so the second fraction in (10.9.2) is positive and so equal to its own absolute value. Hence

\[
\left|\frac{(z - z_4)(z_2 - z_3)}{(z - z_3)(z_2 - z_4)}\right| + \left|\frac{(z - z_2)(z_4 - z_3)}{(z - z_3)(z_4 - z_2)}\right| = 1.
\]

This is known as PTOLEMY’S THEOREM

From the original identity (10.9.2) with \(Z_1\) replacing \(Z\) we can deduce that for four distinct points \(Z_1, Z_2, Z_3, Z_4\)

\[
\frac{Z_1Z_4}{Z_1Z_2} \frac{Z_2Z_3}{Z_2Z_4} + \frac{Z_1Z_2}{Z_1Z_3} \frac{Z_4Z_3}{Z_4Z_2} = 1.
\]

This can be expanded as

\[
\frac{|Z_1, Z_4|}{|Z_1, Z_3|} \text{cis } \alpha \frac{|Z_2, Z_3|}{|Z_2, Z_4|} \text{cis } \beta + \frac{|Z_1, Z_2|}{|Z_1, Z_3|} \frac{|Z_4, Z_3|}{|Z_4, Z_2|} \text{cis } \gamma = 1,
\]

where

\[
\alpha = \angle Z_3Z_1Z_4, \quad \beta = \angle Z_4Z_2Z_3, \quad \gamma = \angle Z_3Z_1Z_2, \quad \delta = \angle Z_4Z_2Z_3.
\]

From this we have that

\[
\frac{|Z_1, Z_4|}{|Z_1, Z_3|} \frac{|Z_2, Z_3|}{|Z_2, Z_4|} \text{cis } (\alpha + \beta) + \frac{|Z_1, Z_2|}{|Z_1, Z_3|} \frac{|Z_4, Z_3|}{|Z_4, Z_2|} \text{cis } (\gamma + \delta) = 1.
\]

We get two relationships on equating the real parts in this and also equating the imaginary parts.

NOTE. For other applications of complex numbers to geometry, see Chapter 11 and Hahn [8].
10.10 ANGLES BETWEEN LINES

10.10.1 Motivation

Since \( \cos(180_\phi + \theta) = -\cos \theta \), \( \sin(180_\phi + \theta) = -\sin \theta \), we have that \( \tan(180_\phi + \theta) = \tan \theta \). Thus results that \( \tan \theta \) is constant do not imply that \( \theta \) is an angle of constant magnitude. To extract more information from such situations, we develop new material. This also deals with the rather abrupt transitions in results such as those in 10.9.1 and 10.9.2.

10.10.2 Duo-sectors

Let \( l_1, l_2 \) be lines intersecting at a point \( Z_1 \). When \( l_1 \neq l_2 \), let \( Z_2, Z_3 \in l_1 \) with \( Z_1 \) between \( Z_2 \) and \( Z_3 \), and let \( Z_4, Z_5 \in l_2 \) with \( Z_1 \) between \( Z_4 \) and \( Z_5 \). Then the union

\[
\mathcal{R}(Z_2Z_1Z_4) \cup \mathcal{R}(Z_3Z_1Z_5)
\]

we shall call a **duo-sector** with side-lines \( l_1 \) and \( l_2 \); we shall denote it by \( \mathcal{D}_1 \). Similarly

\[
\mathcal{R}(Z_2Z_1Z_5) \cup \mathcal{R}(Z_3Z_1Z_4)
\]

is also a duo-sector with side-lines \( l_1 \) and \( l_2 \), and we shall denote it by \( \mathcal{D}_2 \).

![Figure 10.11](image1)

![Figure 10.12](image2)

The mid-line \( l_3 \) of \( Z_2Z_1Z_4 \) is also the mid-line of \( Z_3Z_1Z_5 \) and it lies entirely in \( \mathcal{D}_1 \). The mid-line \( l_4 \) of \( Z_2Z_1Z_5 \) is also the mid-line of \( Z_3Z_1Z_4 \) and it lies entirely in \( \mathcal{D}_2 \). We call \( \{l_3, l_4\} \) the **bisectors** of the line pair \( \{l_1, l_2\} \) and use \( l_3 \) to identify \( \mathcal{D}_1 \), \( l_4 \) to identify \( \mathcal{D}_2 \).

In Figure 10.12 suppose that \( \angle Z_2Z_1Z_4^\circ = \angle Z_3Z_1Z_5^\circ = x \) and \( \angle Z_4Z_1Z_3^\circ = y \) then we have \( 2x + 2y = 360 \) and so \( x + y = 180 \). It follows that \( \frac{1}{2}x + \frac{1}{2}y = 90 \) and so \( l_3 \perp l_4 \).

When \( \delta_\phi(Z_1, Z_2, Z_4) > 0 \) we note that

\[
\mathcal{D}_1 = \{ Z \in \Pi : \delta_\phi(Z_1, Z_2, Z) \delta_\phi(Z_1, Z_4, Z) \leq 0 \},
\]

\[
\mathcal{D}_2 = \{ Z \in \Pi : \delta_\phi(Z_1, Z_2, Z) \delta_\phi(Z_1, Z_4, Z) \geq 0 \},
\]

and get a similar characterisation when \( \delta_\phi(Z_1, Z_2, Z_4) < 0 \).

When \( l_1 = l_2 \), we take \( \mathcal{D}_1 = l_1 \); we could also take \( \mathcal{D}_2 = \Pi \) but do not make any use of this.
**10.10.3 Duo-angles**

When $l_1$, $l_2$ are distinct lines, intersecting at $Z_1$, we call the pairs

\[(\{l_1, l_2\}, \mathcal{D}_1), (\{l_1, l_2\}, \mathcal{D}_2),\]

duo-angles, with arms $l_1$, $l_2$; in this $\mathcal{D}_1$, $\mathcal{D}_2$ are the duo-sectors of 10.10.2. We denote these duo-angles by $\alpha_d, \beta_d$, respectively. We call the bisector $l_3$ the indicator of $\alpha_d$, and the bisector $l_4$ the indicator of $\beta_d$. We define the degree-magnitudes of these duo-angles by

\[|\alpha_d|^\circ = |\angle Z_2Z_1Z_4|^\circ = |\angle Z_3Z_1Z_5|^\circ,\]
\[|\beta_d|^\circ = |\angle Z_2Z_1Z_5|^\circ = |\angle Z_3Z_1Z_4|^\circ.\]

If $l_1 \perp l_2$ we have that $|\alpha_d|^\circ = |\beta_d|^\circ = 90$, and we call these right duo-angles.

When $l_1 = l_2$ we take $\alpha_d = (\{l_1, l_2\}, l_1)$ to be a duo-angle with arms $l_1$, $l_1$, and call it a null duo-angle. Its indicator is $l_1$, and we define its degree-measure to be 0. We do not define a straight duo-angle. Thus the measure of a duo-angle $\gamma_d$ always satisfies $0 \leq |\gamma_d|^\circ < 180$.

When $l_1 \neq l_2$ we define

\[
\sin \alpha_d = \sin(\angle Z_2Z_1Z_4) = \sin(\angle Z_3Z_1Z_5),
\]
\[
\cos \alpha_d = \cos(\angle Z_2Z_1Z_4) = \cos(\angle Z_3Z_1Z_5),
\]
\[
\sin \beta_d = \sin(\angle Z_2Z_1Z_5) = \sin(\angle Z_3Z_1Z_4),
\]
\[
\cos \beta_d = \cos(\angle Z_2Z_1Z_5) = \cos(\angle Z_3Z_1Z_4).
\]

For a right duo-angle these have the values 1 and 0, respectively.

When $l_1$ and $l_2$ are not perpendicular, we can define as well $\tan \alpha_d = \frac{\sin \alpha_d}{\cos \alpha_d}$, $\tan \beta_d = \frac{\sin \beta_d}{\cos \beta_d}$.

If $\alpha_d$ is a null duo-angle we define $\sin \alpha_d = 0$, $\cos \alpha_d = 1$, $\tan \alpha_d = 0$.

**10.10.4 Duo-angles in standard position**

![Figure 10.13.](image-url)
We extend our frame of reference \( \mathcal{F} \) by taking in connection with the line pair \( \{OI, OJ\} \) a canonical pair of duo-sectors \( \mathcal{D}_1 \) and \( \mathcal{D}_2 \), with \( \mathcal{D}_1 \) the union of the first and third quadrants \( \mathcal{Q}_1 \) and \( \mathcal{Q}_3 \), and \( \mathcal{D}_2 \) the union of the second and fourth quadrants. 

For any line \( l \) through the origin \( O \), we consider the duo-angle \( \alpha_d \) with side-lines \( OI \) and \( l \), such that the indicator \( m \) of \( \alpha_d \) lies in the duo-sector \( \mathcal{D}_1 \), that is the bisector of the line-pair \( \{OI, l\} \) which lies in the duo-sector of \( \alpha_d \) also lies in \( \mathcal{D}_1 \). We denote by \( \mathcal{DA}(\mathcal{F}) \) the set of such duo-angles, and we say that they are in \textbf{standard position} with respect to \( \mathcal{F} \).

If \( l \neq OI \) and \( Z_4 \equiv (x_4, y_4) \) is a point other than \( O \) on \( l \), then so is the point with coordinates \((-x_4, -y_4)\); thus, without loss of generality, we may assume that \( y_4 > 0 \) in identifying \( l \) as \( OZ_4 \). Then \( Z_4 \in \mathcal{H}_1 \) and

\[
|\alpha_d| = |\angle IOZ_4|, \\
\cos \alpha_d = \cos(\angle IOZ_4) = \frac{x_4}{\sqrt{x_4^2 + y_4^2}}, \\
\sin \alpha_d = \sin(\angle IOZ_4) = \frac{y_4}{\sqrt{x_4^2 + y_4^2}}.
\]

When \( \alpha_d \) is not a right duo-angle, we have

\[
\tan \alpha_d = \frac{y_4}{x_4}.
\]

We identify \( l = OI \) as \( OZ_4 \) where \( Z_4 \equiv (x_4, 0) \) and \( x_4 > 0 \). Thus for the null duo-angle in standard position we have \( \cos \alpha_d = 1 \), \( \sin \alpha_d = 0 \), \( \tan \alpha_d = 0 \). We denote this null duo-angle by \( 0_{d,\mathcal{F}} \) and the right duo-angle in standard position by \( 90_{d,\mathcal{F}} \).

We now note that if \( \alpha_d, \beta_d \in \mathcal{DA}(\mathcal{F}) \) and \( \tan \alpha_d = \tan \beta_d \), then \( \alpha_d = \beta_d \).

\textbf{Proof.} For this we let \( \alpha_d, \beta_d \) have pairs of side-lines \( (OI, OZ_4), (OI, OZ_5) \), respectively, where \( |O, Z_4| = |O, Z_5| = k \), and either \( y_4 > 0 \) or \( x_4 > 0 \), \( y_4 = 0 \), and similarly either \( y_5 > 0 \) or \( x_5 > 0 \), \( y_5 = 0 \). Then neither \( \alpha_d \) nor \( \beta_d \) is \( 90_{d,\mathcal{F}} \) and

\[
\frac{y_4}{x_4} = \frac{y_5}{x_5}, \quad x_4^2 + y_4^2 = x_5^2 + y_5^2 = k^2.
\]

If \( y_4 = 0 \) then \( y_5 = 0 \) and both duo-angles are null. Suppose then that \( y_4 \neq 0 \) so that \( y_4 > 0 \); it follows that \( y_5 > 0 \). Then

\[
k^2 = x_5^2 + y_5^2 = \frac{y_4^2}{y_4^2} x_4^2 + y_5^2 = \frac{y_5^2}{y_4^2} (x_4^2 + y_4^2) = \frac{y_5^2}{y_4^2} k^2.
\]

Hence \( y_5^2 = y_4^2 \), and so \( y_5 = y_4 \). It follows that \( x_5 = x_4 \).
10.10.5 Addition of duo-angles in standard position

To deal with addition of duo-angles in standard position, let $Q \equiv (k,0)$, $R \equiv (0,k)$ for some $k > 0$, and $\alpha_d$ have side-lines $OQ$ and $OZ_4$, $\beta_d$ have side-lines $OQ$ and $OZ_5$, where $|O,Z_4| = |O,Z_5| = k$ and both have their indicators in $D_1$. Without loss of generality, we may suppose that either $y_4 > 0$ or $y_4 = 0$, $x_4 > 0$, and similarly with respect to $(x_5,y_5)$.

![Figure 10.14. Addition of duo-angles.](image)

Then the line through $Q$ which is parallel to $Z_4Z_5$ will meet the circle $C(O;k)$ in a second point, which we denote by $Z_6 \equiv (x_6,y_6)$. The line through $Q$ parallel to $Z_4Z_5$ has parametric equations

$$x = k + t(x_5 - x_4), \quad y = t(y_5 - y_4),$$

and so meets the circle again when $t \neq 0$ satisfies

$$[k + t(x_5 - x_4)]^2 + [t(y_5 - y_4)]^2 = k^2.$$  

This yields

$$t = -\frac{2k(x_5 - x_4)}{(x_5 - x_4)^2 + (y_5 - y_4)^2},$$

and so we find for $(x_6,y_6)$ that

$$x_6 = k\frac{(y_5 - y_4)^2 - (x_5 - x_4)^2}{(x_5 - x_4)^2 + (y_5 - y_4)^2}, \quad y_6 = -2k\frac{(x_5 - x_4)(y_5 - y_4)}{(x_5 - x_4)^2 + (y_5 - y_4)^2}. \quad (10.10.1)$$

We define the sum $\alpha_d + \beta_d = \gamma_d$, where $\gamma_d$ has side-lines $OQ$ and $OZ_6$ and has its indicator in $D_1$. When $Z_4 = Z_5$ we take $QZ_6$ as the line through $Q$ which is parallel to the tangent to the circle at $Z_4$. This is analogous to the modified sum of angles.

It can be checked that

$$\frac{y_6}{k} - \frac{x_5y_4 + x_4y_5}{k^2} = 0, \quad \frac{x_6}{k} - \frac{x_4x_5 - y_4y_5}{k^2} = 0. \quad (10.10.2)$$

To see this we first note that $(y_5 - y_4)^2 + (x_5 - x_4)^2 = 2[k^2 - (x_4x_5 + y_4y_5)]$. Then the numerator in

$$\frac{(x_5 - x_4)(y_5 - y_4)}{x_4x_5 + y_4y_5 - k^2} - \frac{x_5y_4 + x_4y_5}{k^2}$$
Complex coordinates; sensed angles; angles between lines

Ch. 10

is equal to

\[
k^2[(x_5 - x_4)(y_5 - y_4) + x_5y_4 + x_4y_5] - (x_5y_4 + x_4y_5)(x_4x_5 + y_4y_5)
= k^2(x_5y_5 + x_4y_4) - [x_4y_4(x_5^2 + y_5^2) + x_5y_5(x_4^2 + y_4^2)]
= (k^2 - k^2)(x_5y_5 + x_4y_4) = 0.
\]

Similarly the numerator in

\[
\frac{1}{2} \frac{(y_5 - y_4)^2 - (x_5 - x_4)^2}{k^2 - (x_4x_5 + y_4y_5)} \cdot \frac{x_4x_5 - y_4y_5}{k^2}
\]
equals

\[
k^2[(y_5 - y_4)^2 - (x_5 - x_4)^2 - 2(x_4x_5 - y_4y_5)] + 2(x_4x_5 + y_4y_5)(x_4x_5 - y_4y_5)
= k^2[y_5^2 + y_4^2 - x_5^2 - x_4^2] + 2[x_4^2 - y_4^2] - 2y_4^2]
= k^2[y_5^2 + y_4^2 - x_5^2 - x_4^2] + 2[x_4^2k^2 - y_4^2(x_5^2 + y_4^2)]
= k^2[y_5^2 + y_4^2 - x_5^2 - x_4^2 + 2x_4^2 - 2y_4^2] = 0.
\]

To apply these we note that by 10.10.4

\[
\sin \alpha_d = \frac{y_4}{k}, \cos \alpha_d = \frac{x_4}{k}, \sin \beta_d = \frac{y_5}{k}, \cos \beta_d = \frac{x_5}{k}.
\]
The sum \(\gamma_d = \alpha_d + \beta_d\) has side-lines \(OQ\) and \(OZ_6\), and we sub-divide into two major cases. First we suppose that \(x_5y_4 + x_4y_5 > 0\) or equivalently \(|\alpha_d|^\circ + |\beta_d|^\circ < 180\). Then \(y_6 > 0\) and we have

\[
\sin \gamma_d = \frac{y_6}{k}, \cos \gamma_d = \frac{x_6}{k}.
\]

It follows from (10.10.2) that

\[
\begin{align*}
\sin(\alpha_d + \beta_d) &= \sin \alpha_d \cos \beta_d + \cos \alpha_d \sin \beta_d, \\
\cos(\alpha_d + \beta_d) &= \cos \alpha_d \cos \beta_d - \sin \alpha_d \sin \beta_d.
\end{align*}
\]

Secondly we suppose that \(x_5y_4 + x_4y_5 < 0\) or equivalently \(|\alpha_d|^\circ + |\beta_d|^\circ > 180\). Then \(y_6 < 0\) so we have

\[
\sin \gamma_d = -\frac{y_6}{k}, \cos \gamma_d = -\frac{x_6}{k}.
\]

It follows from (10.10.2) that

\[
\begin{align*}
-\sin(\alpha_d + \beta_d) &= \sin \alpha_d \cos \beta_d + \cos \alpha_d \sin \beta_d, \\
-\cos(\alpha_d + \beta_d) &= \cos \alpha_d \cos \beta_d - \sin \alpha_d \sin \beta_d.
\end{align*}
\]

There is a further case when \(x_5y_4 + x_4y_5 = 0\) and we obtain these formulae according as \(x_4x_5 - y_4y_5\) is positive or negative, respectively. Thus the addition formulae for sine and cosine of duo-angles are more complicated than those of angles.
### 10.10.6 Addition formulae for tangents of duo-angles

(i) We first note that if \( \alpha_d, \beta_d \in D.\mathcal{A}(\mathbb{P}) \) and \( \alpha_d + \beta_d = 90_d \), neither duo-angle being null or right, then \( \tan \alpha_d \tan \beta_d = 1 \). For we have that \( x_6 = 0 \), so that by (10.10.2) \( x_4x_5 - y_4y_5 = 0 \) and thus

\[
\frac{y_4 y_5}{x_4 x_5} = 1.
\]

(ii) Next we note that, as \( \tan \alpha_d = \sin \alpha_d / \cos \alpha_d \), it follows from the above addition formulae for cosine and sine that

\[
\tan(\alpha_d + \beta_d) = \frac{\tan \alpha_d + \tan \beta_d}{1 - \tan \alpha_d \tan \beta_d},
\]

provided that 0 does not occur in a denominator, that is provided none of \( \alpha_d, \beta_d, \alpha_d + \beta_d \) is a right duo-angle; this can be done separately for the cases considered in 10.10.5. In fact this addition formula for the tangent function can be verified without subdivision into cases, as

\[
\frac{y_6}{x_6} = -2 \frac{(y_5 - y_4)(x_5 - x_4)}{(y_5 - y_4)^2 - (x_5 - x_4)^2},
\]

and we wish to show that this is equal to

\[
\frac{y_5/x_5 + y_4/x_4}{1 - y_4y_5/x_4x_5} = \frac{x_4y_5 + x_5y_4}{x_4x_5 - y_4y_5}.
\]  

(10.10.3)

On subtracting the first of these expressions from the second, we obtain a quotient the numerator of which is equal to

\[
(x_4y_5 + x_5y_4)(y_5 - y_4)^2 - (x_5 - x_4)^2 + 2(x_4x_5 - y_4y_5)(y_5 - y_4)(x_5 - x_4)
\]

\[
= (x_4y_5 + x_5y_4)(y_5^2 + y_4^2 - x_5^2 - x_4^2 + 2(x_4x_5 - y_4y_5))
\]

\[
+ 2(x_4x_5 - y_4y_5)[x_4y_4 + x_5y_5 - (x_4y_5 + x_5y_4)]
\]

\[
= (x_4y_5 + x_5y_4)(y_5^2 + y_4^2 - x_5^2 - x_4^2 + 2(x_4x_5 - y_4y_5)(x_4y_4 + x_5y_5)
\]

\[
= (x_4y_5 + x_5y_4)(y_5^2 + y_4^2 - x_5^2 - x_4^2 + 2(x_4x_5y_5 - y_4x_4y_5 + x_5^2y_4 - y_5^2x_4y)
\]

\[
= (x_4^2 + y_4^2)(x_4y_5 - x_5y_4) = 0,
\]

as \( x_4^2 + y_4^2 = x_5^2 + y_5^2 = k^2 \). This identity then implies the standard addition formula for the tangents of duo-angles.

(iii) We also wish to show that

\[
\tan(\alpha_d + 90_d \mathbb{P}) = -\frac{1}{\tan \alpha_d},
\]

when \( \alpha_d \) is neither null nor right. For with \( x_5 = 0, y_5 = k \) (10.10.1) gives

\[
x_6 = k \frac{(k - y_4)^2 - x_4^2}{x_4^2 + (k - y_4)^2},
\]

\[
y_6 = 2k \frac{-x_4(k - y_4)}{x_4^2 + (k - y_4)^2},
\]
so that
\[
\frac{y_6}{x_6} = \frac{2x_4(k - y_4)}{(k - y_4)^2 - x_4^2}.
\]

Then
\[
\frac{y_6 y_4}{x_6 x_4} = 2 \frac{y_4(k - y_4)}{k^2 - 2ky_4 + y_4^2 - x_4^2} = 2 \frac{y_4(k - y_4)}{2y_4^2 - 2ky_4} = -1.
\]

10.10.7  Associativity of addition of duo-angles

With the notation of 10.10.5, suppose that \(\alpha_d\), \(\beta_d\) and \(\gamma_d\) are duo-angles in \(\mathcal{D}(\mathcal{A}(F))\), with pairs side-lines \((OQ, OZ_4)\), \((OQ, OZ_5)\), \((OQ, OZ_6)\), respectively. We wish to consider the sums \((\alpha_d + \beta_d) + \gamma_d\) and \(\alpha_d + (\beta_d + \gamma_d)\). We suppose that \(\alpha_d + \beta_d\) has side-lines \((OQ, OZ_7)\) and that \((\alpha_d + \beta_d) + \gamma_d\) has side-lines \((OQ, OZ_9)\). Similarly we suppose that \(\beta_d + \gamma_d\) has side-lines \((OQ, OZ_8)\) and \(\alpha_d + (\beta_d + \gamma_d)\) has side-lines \((OQ, OZ_{10})\). Then by (10.10.2) applied several times we have that

\[
y_7 = \frac{x_5 y_4 + x_4 y_5}{k}, \quad x_7 = \frac{x_4 x_5 - y_4 y_5}{k},
\]

\[
y_9 = \frac{x_6 y_7 + x_7 y_6}{k} = \frac{x_6}{k} \frac{x_5 y_4 + x_4 y_5}{k} + \frac{x_4 x_5 - y_4 y_5}{k} y_6
\]

\[
= \frac{x_6 (x_5 y_4 + x_4 y_5) + (x_4 x_5 - y_4 y_5) y_6}{k^2}
\]

\[
x_9 = \frac{x_7 x_6 - y_7 y_6}{k} = \frac{x_4 x_5 - y_4 y_5}{k} x_6 - \frac{x_4 x_5 + x_4 y_5}{k} y_6
\]

\[
= \frac{(x_4 x_5 - y_4 y_5) x_6 - (x_5 y_4 + x_4 y_5) y_6}{k^2}.
\]

Similarly

\[
y_8 = \frac{x_6 y_5 + x_5 y_6}{k}, \quad x_8 = \frac{x_5 x_6 - y_5 y_6}{k},
\]

\[
y_{10} = \frac{x_8 y_4 + x_4 y_8}{k} = \frac{x_8 (x_5 y_6 - y_5 y_6) y_4 + x_4 (x_6 y_5 + x_5 y_6)}{k}
\]

\[
= \frac{(x_5 x_6 - y_5 y_6) y_4 + x_4 (x_6 y_5 + x_5 y_6)}{k^2}
\]

\[
x_{10} = \frac{x_4 x_8 - y_4 y_8}{k} = \frac{x_4 (x_5 x_6 - y_5 y_6) - y_4 (x_6 y_5 + x_5 y_6)}{k}
\]

\[
= \frac{x_4 (x_5 x_6 - y_5 y_6) - y_4 (x_6 y_5 + x_5 y_6)}{k^2}.
\]

From these we can see that \(Z_9 = Z_{10}\) and so we have that

\[(\alpha_d + \beta_d) + \gamma_d = \alpha_d + (\beta_d + \gamma_d).\]

Thus addition of duo-angles is associative on \(\mathcal{D}(\mathcal{A}(F))\).
10.10.8 Group properties of duo-angles; sensed duo-angles

We note the following properties of addition of duo-angles:-

(i) Given any duo-angles $\alpha_d$, $\beta_d$ in $\mathcal{DA}(\mathcal{F})$, the sum $\alpha_d + \beta_d$ is a unique object $\gamma_d$ and it lies in $\mathcal{DA}(\mathcal{F})$.

(ii) Addition of duo-angles is commutative, that is

$$\alpha_d + \beta_d = \beta_d + \alpha_d,$$

for all $\alpha_d$, $\beta_d \in \mathcal{DA}(\mathcal{F})$.

(iii) Addition of duo-angles is associative on $\mathcal{DA}(\mathcal{F})$.

(iv) The null angle $0_{d,\mathcal{F}}$ is a neutral element for $+$ on $\mathcal{DA}(\mathcal{F})$.

(v) Each $\alpha_d \in \mathcal{DA}(\mathcal{F})$ has an additive inverse in $\mathcal{DA}(\mathcal{F})$.

**Proof.**

(i) This is evident from the definition.

(ii) This is evident as the addition is symmetrical in the roles of the two duo-angles.

(iii) This was established in 10.10.7.

(iv) For $\alpha_d + 0_{d,\mathcal{F}} = \alpha_d$, for all $\alpha_d \in \mathcal{DA}(\mathcal{F})$.

(v) With the notation of 10.10.5 let $Z_5 = s_{OJ}(Z_4)$ so that $Z_5 \equiv (-x_4, y_4)$, and let $\delta_d$ be the duo-angle in $\mathcal{DA}(\mathcal{F})$ with arms $OI, OZ_5$. Then, straightforwardly, $\alpha_d + \delta_d = 0_{d,\mathcal{F}}$. Thus this duo-angle $\delta_d$ is an additive inverse for $\alpha_d$ in $\mathcal{DA}(\mathcal{F})$. We denote it by $-\alpha_d$.

These properties show that we have a commutative group. We note that

$$\sin(-\alpha_d) = \frac{y_4}{k} = \sin \alpha_d, \quad \cos(-\alpha_d) = -\frac{x_4}{k} = -\cos \alpha_d,$$

$$\tan(-\alpha_d) = -\frac{y_4}{x_4} = -\tan \alpha_d.$$

If $\alpha = \angle_{\mathcal{F}} QOZ_4$ is a wedge-angle in $\mathcal{A}(\mathcal{F})$, with $Z_4 \equiv (x_4, y_4)$ and $y_4 > 0$, we recall that $-\alpha = \angle_{\mathcal{F}} QOZ_6$ where $Z_6 = s_{OJ}(Z_4) \equiv (x_4, -y_4)$. If $\alpha_d$ is the duo-angle in $\mathcal{DA}(\mathcal{F})$ with side-lines $(OQ, OZ_4)$ then $-\alpha_d$ is the duo-angle in $\mathcal{DA}(\mathcal{F})$ with side-lines $(OQ, OZ_5)$ where $Z_5 = s_{OJ}(Z_4) \equiv (-x_4, y_4)$. This inverse angle and inverse duo-angle are linked in that $OZ_5 = OZ_6$ and so $|\alpha| = |\alpha_d| + 180$.

We define $\beta_d - \alpha_d = \beta_d + (-\alpha_d)$, and this is the duo-angle in standard position with side-lines $OQ$ and $OZ_7$, where $Z_7 \equiv (x_7, y_7)$ is the point where the line through $Q$ and parallel to $Z_5s_{OJ}(Z_4)$ meets the circle $\mathcal{C}(O; k)$ again. We call $\beta_d - \alpha_d$ the **difference of two duo-angles** and also a **sensed duo-angle** with side-lines $OZ_4, OZ_5$ and denote it by $\angle_{\mathcal{F}}(OZ_4, OZ_5)$. If $\mathcal{F}'$ is any frame of reference obtained from $\mathcal{F}$ by translation, we also define

$$\angle_{\mathcal{F}'}(OZ_4, OZ_5) = \angle_{\mathcal{F}}(OZ_4, OZ_5).$$

Earlier names for this were a ‘complete angle’ and a ‘cross’; see Forder [7] for applications and exercises, and Forder [6, pages 120–121, 151–154] for applications,
the terminology used being ‘cross’. Sensed duo-angles were also used by Johnson [9, pages 11–15] under the name of ‘directed angles’.

We have

$$\tan(\beta_d - \alpha_d) = \frac{\tan \beta_d - \tan \alpha_d}{1 + \tan \alpha_d \tan \beta_d},$$

provided none of $\alpha_d, \beta_d, \beta_d - \alpha_d$ is a right duo-angle. For a coordinate formula to utilise this we replace $x_4$ by $-x_4$ in (10.10.3) and translate to parallel axes through $Z_1$. Thus for $\gamma_d = \angle \varphi(Z_1Z_4, Z_1Z_5)$ we have

$$\tan \gamma_d = \frac{y_5 - y_1}{x_5 - x_1} - \frac{y_4 - y_1}{x_4 - x_1},$$

when $\gamma_d$ is not right, and

$$1 + \frac{y_5 - y_1}{x_5 - x_1} \frac{y_4 - y_1}{x_4 - x_1} = 0$$

when it is.

**10.10.9 An application**

For fixed points $Z_4$ and $Z_5$, consider the locus of points $Z$ such that $\angle \varphi(ZZ_4, ZZ_5)$ has constant magnitude. If it is a right duo-angle we will have

$$1 + \frac{y_5 - y_1}{x_5 - x_1} \frac{y_4 - y_1}{x_4 - x_1} = 0,$$

and so the points $Z \notin Z_4Z_5$ lie on the circle on $[Z_4, Z_5]$ as diameter. Otherwise, we have that

$$1 + \frac{y_5 - y}{x_5 - x} \frac{y_4 - y}{x_4 - x} = 1 - \lambda,$$

for some $\lambda \neq 1$, and then the points $Z \notin Z_4Z_5$ lie on a circle which passes through $Z_4$ and $Z_5$. In fact we obtain a set of coaxal circles through $Z_4$ and $Z_5$. This should be compared with 7.5.1 and 10.9.1.

**10.11 A CASE OF PASCAL’S THEOREM,**

**1640**

**10.11.1**

Let $Z_1, W_1, Z_2, W_2$ be distinct points on the circle $\mathcal{C}(O;k)$. Then $Z_1W_2 \parallel W_1Z_2$ if and only if $\angle \varphi Z_2OW_2 = \angle \varphi Z_1OW_1$.

**Proof.** We let $z_1 \sim k\cos \theta_1$, $z_2 \sim k\cos \theta_2$, $w_1 \sim k\cos \phi_1$, $w_2 \sim k\cos \phi_2$. Then $Z_1W_2$ and $W_1Z_2$ are parallel if and only if

$$\frac{k\cos \phi_2 - k\cos \theta_1}{k\cos \theta_2 - k\cos \phi_1} = t$$
for some \( t \neq 0 \) in \( R \). By 9.4.1 the left-hand side is equal to

\[
\frac{\cos \phi_2 - \cos \theta_1 + t(\sin \phi_2 - \sin \theta_1)}{\cos \theta_2 - \cos \phi_1 + t(\sin \theta_2 - \sin \phi_1)}
\]

\[
= \frac{-2\sin(\frac{1}{2} \phi_2 + \frac{1}{2} \theta_1) \sin(\frac{1}{2} \phi_2 - \frac{1}{2} \theta_1) + 2t \cos(\frac{1}{2} \phi_2 + \frac{1}{2} \theta_1) \cos(\frac{1}{2} \phi_2 - \frac{1}{2} \theta_1)}{-2\sin(\frac{1}{2} \theta_2 + \frac{1}{2} \phi_1) \sin(\frac{1}{2} \theta_2 - \frac{1}{2} \phi_1) + 2t \cos(\frac{1}{2} \theta_2 + \frac{1}{2} \phi_1) \cos(\frac{1}{2} \theta_2 - \frac{1}{2} \phi_1)}
\]

\[
= \frac{\sin(\frac{1}{2} \phi_2 - \frac{1}{2} \theta_1) \cos(\frac{1}{2} \theta_2 + \frac{1}{2} \phi_1)}{\sin(\frac{1}{2} \theta_2 - \frac{1}{2} \phi_1)}
\]

\[
= \frac{\sin(\frac{1}{2} \phi_2 - \frac{1}{2} \theta_1) \cos(\frac{1}{2} \theta_2 + \frac{1}{2} \phi_1)}{\sin(\frac{1}{2} \theta_2 - \frac{1}{2} \phi_1)} \cos(\frac{1}{2} \theta_2 - \frac{1}{2} \phi_1).
\]

Thus

\[
\cos(\frac{1}{2} \phi_2 + \frac{1}{2} \theta_1 - \frac{1}{2} \theta_2 - \frac{1}{2} \phi_1) = \frac{\sin(\frac{1}{2} \theta_2 - \frac{1}{2} \phi_1) \cos(\frac{1}{2} \theta_2 + \frac{1}{2} \phi_1)}{\sin(\frac{1}{2} \phi_2 - \frac{1}{2} \theta_1)} \cdot t.
\]

But the absolute value here is 1, so the right-hand side is \( \pm 1 \). Thus we have either

\[
\frac{1}{2} \phi_2 + \frac{1}{2} \theta_1 - \frac{1}{2} \theta_2 - \frac{1}{2} \phi_1 = 0 \text{ or } \phi_2 - \phi_1 = \theta_2 - \theta_1 \text{ and so } \angle Z_2 O W_2 = \angle Z_1 O W_1.
\]

In each case, we have that \( \phi_2 - \phi_1 = \theta_2 - \theta_1 \) and so \( \angle Z_2 O W_2 = \angle Z_1 O W_1 \).

**Corollary.** If \( (Z_1, W_1), (Z_2, W_2), (Z_3, W_3) \) are distinct pairs of points all on a circle and such that \( Z_1 W_2 \parallel W_1 Z_2 \) and \( Z_2 W_3 \parallel W_2 Z_3 \) then \( Z_1 W_3 \parallel W_1 Z_3 \).

**Proof.** This follows immediately from the last subsection. It is a case of what is known as **Pascal’s theorem**.

\[
\text{Figure 10.15. A case of Pascal’s theorem}
\]

**COROLLARY.** If \( (Z_1, W_1), (Z_2, W_2), (Z_3, W_3), (Z_4, W_4) \) are four distinct pairs of points all on a circle and such that

\[
Z_1 W_2 \parallel W_1 Z_2, \quad Z_2 W_3 \parallel W_2 Z_3, \quad Z_3 W_4 \parallel W_3 Z_4,
\]

then \( Z_1 W_4 \parallel W_1 Z_4 \).
Complex coordinates; sensed angles; angles between lines

178

Ch. 10

Figure 10.16. Very symmetrical cases.

Proof. For from the first two we deduce that $Z_1W_3 \parallel W_1Z_3$ and on combining this with the third relation we obtain the conclusion.

NOTE. Clearly this last result can be extended to any number of pairs of points on a circle.

10.11.2

Starting more generally than in the last subsection, for pairs of distinct points let $(Z_1, W_1) \sim (Z_2, W_2)$ if and only if $Z_1W_2 \parallel W_1Z_2$. Then clearly the relation $\sim$ is reflexive and symmetric. We ask when it is also transitive and thus an equivalence relation.

Now if $Z_1 \equiv (x_1, y_1), Z_2 \equiv (x_2, y_2), W_1 \equiv (u_1, v_1), W_2 \equiv (u_2, v_2)$, we have $(Z_1, W_1) \sim (Z_2, W_2)$ if and only if

$$v_2x_2 - u_2y_2 = (v_2 - y_1)(x_2 - u_1) = (u_2 - x_1)(y_2 - v_1). \quad (10.11.1)$$

Similarly we have $(Z_2, W_2) \sim (Z, W)$ if and only if

$$v_2x_2 - u_2y_2 = (v_1 - y_2)(x_2 - u_2) = (u_1 - x_2)(y_1 - v_2). \quad (10.11.2)$$

We wish (10.11.1) and (10.11.2) to imply that

$$v_2x_2 - u_2y_2 = (v_1 - y_1)(x_2 - u_1) = (u_1 - x_1)(y_1 - v_2). \quad (10.11.3)$$

From (10.11.1) we have that

$$v_2x_2 - u_2y_2 = u_1v_2 - u_2v_1 + x_2y_1 - x_1y_2 + x_1v_1 - y_1u_1,$$

and from (10.11.2)

$$v_2x_2 - u_2y_2 = uv_2 - u_2v + x_2y - xy_2 + vx - uy,$$

so together these give

$$vx - uy = u_1v_2 - u_2v_1 + x_2y_1 - x_1y_2 + x_1v_1 - y_1u_1 - uv_2 + u_2v - x_2y + xy_2.$$
and so our condition for transitivity is got by equating the two right-hand sides here. This turns out to be 
\( \delta_\sigma(Z_1, Z_2, Z) = \delta_\sigma(W_1, W_2, W) \).

Now (10.11.2) and (10.11.3) simultaneously give a transformation under which

\[ Z \rightarrow W \] as we see by writing them as

\[
\frac{v - y_2}{u - x_2} = \frac{y - v_2}{x - u_2}, \quad \frac{v - y_1}{u - x_1} = \frac{y - v_1}{x - u_1}.
\] (10.11.4)

On solving for \( u \) and \( v \) in this we obtain

\[
u = \frac{y - y_1 + x_1 \frac{y - v_1}{x - u_1} - x_2 \frac{y - v_2}{x - u_2}}{\frac{y - v_1}{x - u_1} - \frac{y - v_2}{x - u_2}},
\]

\[
v = \frac{x_2 - x_1 + y_1 \frac{x - u_1}{y - v_1} - y_2 \frac{x - u_2}{y - v_2}}{\frac{x - u_1}{y - v_1} - \frac{x - u_2}{y - v_2}}.
\]

To utilize this transformation we consider loci with equations of the form

\[
2h \frac{y - v_2}{x - u_2} \frac{y - v_1}{x - u_1} + 2g \frac{y - v_2}{x - u_2} + 2f \frac{y - v_1}{x - u_1} + c = 0.
\] (10.11.5)

Under the transformation this maps into the locus with equation

\[
2h \frac{v - y_2}{u - x_2} \frac{v - y_1}{u - x_1} + 2g \frac{v - y_2}{u - x_2} + 2f \frac{v - y_1}{u - x_1} + c = 0.
\] (10.11.6)

On clearing the equation (10.11.5) of fractions we obtain

\[
2h(y - v_2)(y - v_1) + 2g(y - v_2)(x - u_1) + 2f(y - v_1)(x - u_2)
\]

\[ + c(x - u_1)(x - u_2) = 0,
\]

from which we see that \( W_1 \) and \( W_2 \) are both on this locus. This equation can be re-arranged as

\[
 cx^2 + 2(g + f)xy + 2hy^2 - (2gv_2 + 2f v_1 + cu_1 + cu_2)x -
(2gu_1 + 2fu_2 + 2hv_1 + 2hv_2)y + 2hv_1 v_2 + 2gu_1 v_2 + 2fu_2 v_1 + cu_1 u_2 = 0.
\] (10.11.7)

Similarly we see that \( Z_1 \) and \( Z_2 \) are on the locus given by (10.11.6), and the equation for it becomes

\[
cu^2 + 2(g + f)uv + 2hv^2 - (2gy_2 + 2fy_1 + cx_1 + cx_2)u -
(2gx_1 + 2fx_2 + 2hy_1 + 2hy_2)v + 2hy_1 y_2 + 2gx_1 y_2 + 2fx_2 y_1 + cx_1 x_2 = 0.
\] (10.11.8)

We note that \( W_1 \) maps to \( Z_1 \) and \( W_2 \) maps to \( Z_2 \) under the transformation in which \( Z \) maps to \( W \).

To identify all the loci that can occur in (10.11.7) and (10.11.8) would take us beyond the concepts of the present course, so we concentrate on when they represent circles.
Now (10.11.7) is a circle when \( c = 2h \neq 0 \) and \( g = -f \). The equation then becomes

\[
x^2 + y^2 + \left[ \frac{g}{h}(v_1 - v_2) - u_1 - u_2 \right] x + \left[ \frac{g}{h}(u_2 - u_1) - v_1 - v_2 \right] y \\
+ \frac{g}{h}(u_1 v_2 - u_2 v_1) + u_1 u_2 + v_1 v_2 = 0. \quad (10.11.9)
\]

This is the set of circles which pass through the points \( W_1 \) and \( W_2 \), a set of coaxal circles. The corresponding equation for the second locus is

\[
u^2 + v^2 + \left[ \frac{g}{h}(y_1 - y_2) - x_1 - x_2 \right] u + \left[ \frac{g}{h}(x_2 - x_1) - y_1 - y_2 \right] v \\
+ \frac{g}{h}(x_1 y_2 - x_2 y_1) + x_1 x_2 + y_1 y_2 = 0, \quad (10.11.10)
\]

and this gives the set of coaxal circles passing through \( Z_1 \) and \( Z_2 \).

\[\begin{tikzpicture}
    \draw (0,0) circle (2cm);
    \draw (-2,0) -- (2,0);
    \draw (0,-2) -- (0,2);
    \node at (0,0) [above] {Z};
    \node at (-2,0) [below left] {W};
    \node at (2,0) [below right] {W_2};
    \node at (0,-2) [below] {Z_1};
    \node at (0,2) [above] {Z_2};
    \node at (0,-2) [below] {W};
\end{tikzpicture}\]

Figure 10.17. Pascal result for two circles.

\[\begin{align*}
    \frac{n(y_2 - v) - l(x_2 v - y_2 u)}{n(x_2 - u) + m(x_2 v - y_2 u)} &= \frac{n(v_2 - y) - l(u_2 y - v_2 x)}{n(u_2 - x) + m(u_2 y - v_2 x)}, \\
    \frac{n(y_1 - v) - l(x_1 v - y_1 u)}{n(x_1 - u) + m(x_1 v - y_1 u)} &= \frac{n(v_1 - y) - l(u_1 y - v_1 x)}{n(u_1 - x) + m(u_1 y - v_1 x)}. 
\end{align*}\]

\[\text{Exercises}\]

10.1 Prove the result of Varignon (1731) that if \( A, B, C, D \) are the vertices of a convex quadrilateral and

\[P = \text{mp}(A, B), \quad Q = \text{mp}(B, C), \quad R = \text{mp}(C, D), \quad S = \text{mp}(D, A),\]
then $P, Q, R, S$ are the vertices of a parallelogram.

10.2 If $Z_1 \sim z_1, Z_2 \sim z_2$ and $Z_3 \sim z_3$ are non-collinear points show that

$$z_1 (\bar{z}_3 - \bar{z}_2) + z_2 (\bar{z}_1 - \bar{z}_3) + z_3 (\bar{z}_2 - \bar{z}_1) = 4i \delta (Z_1, Z_2, Z_3) \neq 0.$$ 

10.3 Let $A \sim a, B \sim b$, $C \sim c$ be non-collinear points and $P \sim p$ a point such that $AP, BP, CP$ meet $BC, CA, AB$ at $D \sim d$, $E \sim e$, $F \sim f$, respectively. Show for sensed ratio that

$$\frac{BD}{DC} = \frac{p(\bar{b} - \bar{a}) + \bar{p}(a - b) + b\bar{a} - a\bar{b}}{p(\bar{a} - \bar{c}) + \bar{p}(c - a) + a\bar{c} - c\bar{a}},$$

and hence prove Ceva’s theorem that

$$\frac{BD \ CE \ AF}{DC \ EA \ FB} = 1.$$ 

10.4 Let $A \sim a, B \sim b$, $C \sim c$ be non-collinear points. Given any point $P \sim p$, show that as $(c - a)/(b - a)$ is non-real there exist unique real numbers $y$ and $z$ such that $p - a = y(b - a) + z(c - a)$, and so $p = xa + yb + zc$ where $x + y + z = 1$. Show that if $AP$ meets $BC$ it is in a point $D \sim d$ such that

$$d = \frac{1}{1 + r} b + \frac{r}{1 + r} c,$$

where $r = z/y$. Hence prove Ceva’s theorem that if $D \in BC$, $E \in CA$, $F \in AB$ are such that $AD, BE, CF$ are concurrent, then

$$\frac{BD \ CE \ AF}{DC \ EA \ FB} = 1.$$ 

10.5 Let $A \sim a, B \sim b$, $C \sim c$ be non-collinear points. If $D \sim d, E \sim e$ where

$$d = \frac{1}{1 + \lambda} b + \frac{\lambda}{1 + \lambda} c, \ e = \frac{1}{1 + \mu} c + \frac{\mu}{1 + \mu} a,$$

and $DE$ meets $AB$ it is in a point $F \sim f$ where

$$f = \frac{1}{1 + v} a + \frac{v}{1 + v} b,$$

and $\lambda \mu v = -1$.

Prove Menelaus’ theorem that if $D \in BC$, $E \in CA$, $F \in AB$ are collinear, then

$$\frac{BD \ CE \ AF}{DC \ EA \ FB} = -1.$$
10.6 Let $A, B, C$ be non-collinear points and take $D \in BC$, $E \in CA$, $F \in AB$ such that

\[
\frac{BD}{BC} = r, \quad \frac{CE}{CA} = s, \quad \frac{AF}{AB} = t.
\]

Let $l, m, n$ be, respectively, the lines through $D$, $E$, $F$ which are perpendicular to the side-lines $BC$, $CA$, $AB$. Show that $l, m, n$ are concurrent if and only if

\[
(1 - 2r)|B, C|^2 + (1 - 2s)|C, A|^2 + (1 - 2t)|A, B|^2 = 0.
\]

10.7 If $\mathcal{R}(Z_0)$ is the set of all rotations about the point $Z_0$, show that $(\mathcal{R}(Z_0), \circ)$ is a commutative group.

10.8 Show that the composition of axial symmetries in two parallel lines is equal to a translation, and conversely that each translation can be expressed in this form.

10.9 Prove that $s_{\phi,Z_0} \circ s_{\theta,Z_0} = r_{2(\phi - \theta):Z_0}$.

10.10 Prove that $s_{\phi,Z_0} \circ r_{\theta,Z_0} = s_{\phi - \frac{1}{2}\theta,Z_0}$. Deduce that any rotation about the point $Z_0$ can be expressed as the composition of two axial symmetries in lines which pass through $Z_0$.

10.11 Let $\mathcal{F}_1 \sim \mathcal{F}_2$ if the frame of reference $\mathcal{F}_2$ is positively oriented with respect to $\mathcal{F}_1$. Show that $\sim$ is an equivalence relation.

10.12 Prove the Stewart identity

\[
(z_4 - z_1)^2(z_3 - z_2) + (z_4 - z_2)^2(z_1 - z_3) + (z_4 - z_3)^2(z_2 - z_1)
\]

\[
= - (z_3 - z_2)(z_1 - z_3)(z_2 - z_1).
\]

Interpret this trigonometrically.

10.13 Prove DeMoivre’s theorem that

\[
(cos \alpha + i \sin \alpha)^n = cos(n \alpha) + i \sin(n \alpha),
\]

for all positive integers $n$ and all angles $\alpha \in \mathcal{A}^*(\mathcal{F})$, where $i$ is the complex number satisfying $i^2 = -1$.

10.14 Suppose that $l, m, n$ are distinct parallel lines. Let $Z_1, Z_2, Z_3, Z_4 \in l$ with $Z_1 \neq Z_2$, $Z_3 \neq Z_4$. Suppose that $Z_5, Z_6 \in n, Z_1Z_5, Z_2Z_5$ meet $m$ at $Z_7, Z_8$, respectively, and $Z_3Z_6, Z_4Z_6$ meet $m$ at $Z_9, Z_{10}$, respectively. Prove that then

\[
\frac{Z_9Z_{10}}{Z_7Z_8} = \frac{Z_5Z_4}{Z_1Z_2}.
\]
10.15 If \([Z_1, Z_2, Z_3, Z_4]\) is a parallelogram, \(W\) is a point on the diagonal line \(Z_1Z_3\), a line through \(W\) parallel to \(Z_1Z_2\) meets \(Z_1Z_4\) at \(W_1\) and \(W_2\) respectively, and a line through \(W\) parallel to \(Z_1Z_4\) meets \(Z_1Z_2\) and \(Z_3Z_4\) at \(W_3\) and \(W_4\), respectively, prove that
\[
\delta_{\mathcal{F}}(W, W_4, W_1) = \delta_{\mathcal{F}}(W, W_3, W_2).
\]

10.16 If \(Z_1 \neq Z_2\) and \(\delta_{\mathcal{F}}(Z_1, Z_2, Z_3) = -\delta_{\mathcal{F}}(Z_1, Z_2, Z_4)\), prove that the mid-point of \(Z_3\) and \(Z_4\) is on \(Z_1Z_2\).

10.17 Suppose that \(Z_1, Z_2, Z_3, Z_4\) are points no three of which are collinear. Show that \([Z_1, Z_3] \cap [Z_2, Z_4] \neq \emptyset\) if and only if
\[
\frac{\delta_{\mathcal{F}}(Z_1, Z_2, Z_4)}{\delta_{\mathcal{F}}(Z_3, Z_2, Z_4)} < 0 \quad \text{and} \quad \frac{\delta_{\mathcal{F}}(Z_2, Z_1, Z_3)}{\delta_{\mathcal{F}}(Z_4, Z_1, Z_3)} < 0.
\]

Vector and complex-number methods

11.1 EQUIPOLLENCE

11.1.1

Definition. An ordered pair \((Z_1, Z_2)\) of points in \(\Pi\) is said to be equipollent to the pair \((Z_3, Z_4)\), written symbolically \((Z_1, Z_2) \uparrow (Z_3, Z_4)\), if \(\text{mp}(Z_1, Z_4) = \text{mp}(Z_2, Z_3)\). Thus \(\uparrow\) is a binary relation in \(\Pi \times \Pi\).

Equipollence has the properties:

(i) If \(Z_1 \equiv (x_1, y_1), Z_2 \equiv (x_2, y_2), Z_3 \equiv (x_3, y_4), Z_4 \equiv (x_4, y_4)\), then \((Z_1, Z_2) \uparrow (Z_3, Z_4)\) if and only if \(x_1 + x_4 = x_2 + x_3, y_1 + y_4 = y_2 + y_3\), or equivalently \(x_2 - x_1 = x_4 - x_3, y_2 - y_1 = y_4 - y_3\).

(ii) Given any points \(Z_1, Z_2, Z_3 \in \Pi\), there is a unique point \(Z_4\) such that \((Z_1, Z_2) \uparrow (Z_3, Z_4)\).

(iii) For all \(Z_1, Z_2 \in \Pi\), \((Z_1, Z_2) \uparrow (Z_1, Z_2)\).

(iv) If \((Z_1, Z_2) \uparrow (Z_3, Z_4)\) then \((Z_3, Z_4) \uparrow (Z_1, Z_2)\).

(v) If \((Z_1, Z_2) \uparrow (Z_3, Z_4)\) and \((Z_3, Z_4) \uparrow (Z_5, Z_6)\), then \((Z_1, Z_2) \uparrow (Z_5, Z_6)\).

(vi) If \((Z_1, Z_2) \uparrow (Z_3, Z_4)\) then \((Z_1, Z_3) \uparrow (Z_2, Z_4)\).

(vii) If \((Z_1, Z_2) \uparrow (Z_3, Z_4)\), then \(|Z_1, Z_2| = |Z_3, Z_4|\).

(viii) For all \(Z_1 \in \Pi\), \((Z_1, Z_1) \uparrow (Z_3, Z_4)\) if and only if \(Z_3 = Z_4\).

(ix) If \(Z_1 \neq Z_2\) and \(Z_3 \in l = Z_1Z_2\), then \((Z_1, Z_2) \uparrow (Z_3, Z_4)\) if and only \(Z_4 \in l\), \(|Z_1, Z_2| = |Z_3, Z_4|\) and if \(\leq l\) is the natural order for which \(Z_1 \leq l Z_2\), then \(Z_3 \leq l Z_4\).
(x) If \( Z_1 \neq Z_2 \) and \( Z_3 \notin Z_1Z_2 \), then \( (Z_1, Z_2) \uparrow (Z_3, Z_4) \) if and only if 
\[ [Z_1, Z_2, Z_4, Z_3] \] is a parallelogram.

**Proof.**

(i) By the mid-point formula,
\[
\text{mp}(Z_1, Z_4) = \left( \frac{x_1 + x_4}{2}, \frac{y_1 + y_4}{2} \right), \quad \text{mp}(Z_2, Z_3) = \left( \frac{x_2 + x_3}{2}, \frac{y_2 + y_3}{2} \right),
\]
and the result follows immediately from this.

(ii) By part (i) it is necessary and sufficient that we choose \( Z_4 \) so that \( x_4 = x_2 + x_3 - x_1, \ y_4 = y_2 + y_3 - y_1 \).

(iii) This is immediate as \( x_1 + x_2 = x_1 + x_2, \ y_1 + y_2 = y_1 + y_2 \).

(iv) This is immediate as \( x_2 + x_3 = x_1 + x_4, \ y_2 + y_3 = y_1 + y_4 \).

(v) We are given that 
\[
x_1 + x_4 = x_2 + x_3, \quad y_1 + y_4 = y_2 + y_3,
\]
\[
x_3 + x_6 = x_4 + x_5, \quad y_3 + y_6 = y_4 + y_5.
\]
By addition \( (x_1 + x_6) + (x_3 + x_4) = (x_2 + x_5) + (x_3 + x_4) \), so by cancellation of \( x_3 + x_4 \) we have \( x_1 + x_6 = x_2 + x_5 \). Similarly \( y_1 + y_6 = y_2 + y_5 \) and so the result follows.

(vi) For by (i) above we have \( x_1 + x_4 = x_3 + x_2, \ y_1 + y_4 = y_3 + y_2 \).

(vii) For by (i) above \( (x_2 - x_1)^2 + (y_2 - y_1)^2 = (x_4 - x_3)^2 + (y_4 - y_3)^2 \), and now we apply the distance formula.

(viii) For if \( x_1 = x_2, y_1 = y_2 \), then (i) above is satisfied if and only if \( x_3 = x_4, y_3 = y_4 \).

![Figure 11.1](image-url)

(ix) For suppose first that \( (Z_1, Z_2) \uparrow (Z_3, Z_4) \). Then \( Z_3 \in l \) and
\[ \text{mp}(Z_3, Z_4) \in l, \] so \( Z_4 \in l \). By (vii) above we have \( |Z_1, Z_2| = |Z_3, Z_4| \). Suppose first that \( l \) is not perpendicular to \( OI \) and that, as in 6.4.1(ii), the correspondence between \( \leq l \) and the natural order \( \leq_{OJ} \), under which \( O \leq_{OJ} l \), is direct. Then \( \pi_{OIJ}(Z_1) \leq_{OIJ} \pi_{OIJ}(Z_2) \), so \( x_1 \leq x_2 \). By (i) above \( x_3 \leq x_4 \), and so by this argument traced in reverse we have \( Z_3 \leq l Z_4 \). If the correspondence is indirect, we have \( x_2 \leq x_1, x_4 \leq x_3 \) instead. When \( l \) is perpendicular to \( OI \), we project to \( OJ \) instead and make use of the \( y \)-coordinates.

Conversely suppose that \( Z_4 \in l, \ |Z_1, Z_2| = |Z_3, Z_4| \) and \( Z_3 \leq l Z_4 \). Now \( l \) has parametric equations \( x = x_1 + t(x_2 - x_1), \ y = y_1 + t(y_2 - y_1) \quad (t \in \mathbb{R}) \). Suppose that \( Z_3 \) and \( Z_4 \) have parameters \( t_3, t_4 \), respectively, so that
\[
x_3 = x_1 + t_3(x_2 - x_1), \quad y_3 = y_1 + t_3(y_2 - y_1),
\]
\[
x_4 = x_1 + t_4(x_2 - x_1), \quad y_4 = y_1 + t_4(y_2 - y_1).
\]
Recall that $Z_1, Z_2$ have parameters 0 and 1 and $0 < 1$. As in the last paragraph above, if $l$ is not perpendicular to $OI$ and the correspondence between $\leq l$ and $\leq OI$ is direct, then $x_1 < x_2, x_3 < x_4$; hence $t_3 < t_4$ and we obtain this same conclusion when the correspondence is inverse. When $l$ is perpendicular to $OI$ we project to $OI$ instead, and use the y-coordinates. Moreover

$$|Z_3, Z_4|^2 = [(t_4 - t_3)(x_2 - x_1)]^2 + [(t_4 - t_3)(y_2 - y_1)]^2 = (t_4 - t_3)^2|Z_1, Z_2|^2.$$  

Hence $|t_4 - t_3| = 1$, and so as $t_3 < t_4$ we have $t_4 = 1 + t_3$. Then

$$x_1 + x_4 = 2x_1 + (1 + t_3)(x_2 - x_1), \quad x_2 + x_3 = x_2 + x_1 + t_3(x_2 - x_1)$$

and these are equal. Similarly

$$y_1 + y_4 = 2y_1 + (1 + t_3)(y_2 - y_1), \quad y_2 + y_3 = y_2 + y_1 + t_3(y_2 - y_1)$$

and these are equal. By (i) above we now have $(Z_1, Z_2) \uparrow (Z_3, Z_4)$.

(x) If $[Z_1, Z_2, Z_4, Z_3]$ is a parallelogram, then $mp(Z_1, Z_4) = mp(Z_2, Z_3)$. Conversely suppose that $Z_1 \neq Z_2, Z_3 \notin Z_1Z_2$ and $mp(Z_1, Z_4) = mp(Z_2, Z_3)$. Then $Z_1Z_2, Z_3Z_4$ have equations

$$-(y_2 - y_1)(x - x_1) + (x_2 - x_1)(y - y_1) = 0, \quad -(y_4 - y_3)(x - x_3) + (x_4 - x_3)(y - y_3) = 0.$$  

By (i) above, $x_2 = x_4 - x_3, y_2 - y_1 = y_4 - y_3$, so these lines are parallel. Similarly $Z_1Z_3, Z_2Z_4$ have equations

$$-(y_3 - y_1)(x - x_1) + (x_3 - x_1)(y - y_1) = 0, \quad -(y_4 - y_2)(x - x_2) + (x_4 - x_2)(y - y_2) = 0,$$

and by (i) above $x_3 = x_4 - x_2, y_3 - y_1 = y_4 - y_2$, so that these lines are parallel. Thus $[Z_1, Z_2, Z_4, Z_3]$ is a parallelogram.

### 11.2 SUM OF COUPLES, MULTIPLICATION OF A COUPLE BY A SCALAR

#### 11.2.1
**Definition.** For $O \in \Pi$, let $\mathcal{V}(\Pi; O)$ be the set of all couples $(O, Z)$ for $Z \in \Pi$. We define the sum $(O, Z_1) + (O, Z_2)$ of two couples to be $(O, Z_3)$ where $mp(O, Z_3) = mp(Z_1, Z_2)$, so that $(O, Z_1) \uparrow (Z_2, Z_3)$. Thus + is a binary operation in $\mathcal{V}(\Pi; O)$.

We define the product by a number or scalar $t.(O, Z_1)$, of a number $t \in \mathbb{R}$ and a couple, to be a couple $(O, Z_4)$ as follows. When $Z_1 = O$ we take $Z_4 = O$ for all $t \in \mathbb{R}$. When $Z_1 \neq O$ we take $Z_4$ to be in the line $l = OZ_1$ and with $|O, Z_4| = |t||O, Z_1|$; furthermore if $\leq t$ is the natural order for which $O \leq t Z_1$, we take $O \leq t Z_4$ when $t \geq 0$, and $Z_4 \leq t O$ when $t < 0$. Thus product by a number is a function on $\mathbb{R} \times \mathcal{V}(\Pi; O)$ into $\mathcal{V}(\Pi; O)$.

**COMMENT.** To prove by synthetic means the basic properties of couples listed in 11.2.2 and 11.3.1, would be very laborious in covering all the cases. We establish instead initial algebraic characterizations which allow an effective algebraic approach.

*If $O$ is the origin and $Z_1 \equiv (x_1, y_1), Z_2 \equiv (x_2, y_2)$, then*

(i) $(O, Z_1) + (O, Z_2) = (O, Z_3)$ where $Z_3 \equiv (x_1 + x_2, y_1 + y_2)$.

(ii) $t.(O, Z_1) = (O, Z_4)$ where $Z_4 \equiv (tx_1, ty_1)$.

**Proof.**

(i) For this we have $0 + x_3 = x_1 + x_2$, $0 + y_3 = y_1 + y_2$.

(ii) We verify this as follows. Let $(x_4, y_4) = (tx_1, ty_1)$. When $(x_1, y_1) = (0, 0)$ clearly we have $(x_4, y_4) = (x_1, y_1)$. When $(x_1, y_1) \neq (0, 0)$, clearly $Z_4 \in OZ_1$ while

$$|O, Z_4|^2 = (tx_1)^2 + (ty_1)^2 = t^2|O, Z_1|^2.$$  

Now if $l$ is not perpendicular to $OI$ and the correspondence between the natural order $\leq l$ and the natural order $\leq_O I$ on $OI$, under which $O \leq_O I$, is direct then $x_1 < x_2$. Thus when $t > 0$, we have $tx_1 > 0$ and so $O \leq t Z_4$; when $t < 0$, we have $tx_1 < 0$ and so $Z_4 \leq t O$. When the correspondence between the natural orders is inverse, we reach the same conclusion. When $l$ is perpendicular to $OI$ we project to $OI$ instead.

### 11.2.2 Vector space over $\mathbb{R}$

**Definition.** A triple $(\mathcal{V}, +, \cdot)$ is said to be a vector space over $\mathbb{R}$ if the following hold:-

(i) First, $+$ is a binary operation in $\mathcal{V}$.

(ii) For all $a, b, c \in \mathcal{V}$, $(a + b) + c = a + (b + c)$.

(iii) There is an $0 \in \mathcal{V}$ such that for all $a \in \mathcal{V}$,

$$a + 0 = a, \quad 0 + a = a.$$

(iv) Corresponding to each $a \in \mathcal{V}$, there is some $-a \in \mathcal{V}$ such that

$$(-a) + a = 0, \quad a + (\overline{a}) = 0.$$
Sec. 11.2  Sum of couples, multiplication of a couple by a scalar  189

(v) For all \( a, b \in \mathcal{V} \), \( a + b = b + a \).

(vi) Next, \( \mathbf{R} \times \mathcal{V} \to \mathcal{V} \) is a function.

(vii) For all \( a \in \mathcal{V} \) and all \( t_1, t_2 \in \mathbf{R} \), \( (t_2 t_1) a = (t_2 t_1).a \).

(viii) For all \( a, b \in \mathcal{V} \) and all \( t \in \mathbf{R} \), \( t \cdot (a + b) = t \cdot a + t \cdot b \).

(ix) For all \( a \in \mathcal{V} \) and all \( t_1, t_2 \in \mathbf{R} \), \( (t_1 + t_2) a = t_1 a + t_2 a \).

(x) For all \( a \in \mathcal{V} \), \( 1 \cdot a = a \).

We then have the following result.

\( (\mathcal{V}; O, +, \cdot) \) is a vector space over \( \mathbf{R} \).

**Proof.**

(i) This has been covered already in 11.2.1.

(ii) Now \( (O, Z_1) + (O, Z_2) = (O, Z_4) \) where \( (x_4, y_4) = (x_1 + x_2, y_1 + y_2) \). Then

\[
[(O, Z_1) + (O, Z_2)] + (O, Z_3) = (O, Z_4) + (O, Z_3) = (O, Z_5),
\]

where

\[
(x_5, y_5) = (x_4 + x_3, y_4 + y_3) = ((x_1 + x_2) + x_3, (y_1 + y_2) + y_3).
\]

Similarly \( (O, Z_2) + (O, Z_3) = (O, Z_6) \) where \( (x_6, y_6) = (x_2 + x_3, y_2 + y_3) \), and so

\[
(O, Z_1) + [(O, Z_2) + (O, Z_3)] = (O, Z_1) + (O, Z_6) = (O, Z_7).
\]

(iii) For any \( Z_1 \in \Pi \), \( (O, Z_1) + (O, O) = (O, Z_2) \) where \( (x_2, y_2) = (x_1 + 0, y_1 + 0) = (x_1, y_1) \), so that \( Z_2 = Z_1 \). Similarly \( (O, O) + (O, Z_1) = (O, Z_3) \) where \( (x_3, y_3) = (0 + x_1, 0 + y_1) = (x_1, y_1) \), so that \( Z_3 = Z_1 \).

(iv) Now \( (O, Z_1) + (O, Z_2) = (O, Z_3) \), \( (O, Z_2) + (O, Z_1) = (O, Z_4) \) where \( (x_3, y_3) = (x_1 + x_2, y_1 + y_2) \) and \( (x_4, y_4) = (x_2 + x_3, y_2 + y_3) \). Clearly \( Z_3 = Z_4 \).

(v) If \( (x_2, y_2) = (-x_1, -y_1) \), then \( (O, Z_1) + (O, Z_2) = (O, Z_3) \) where

\[
(x_3, y_3) = (x_1 - x_1, y_1 - y_1) = (0, 0); \text{ hence } Z_3 = O. \text{ Similarly } (O, Z_2) + (O, Z_1) = (O, Z_4) \text{ where } (x_4, y_4) = (-x_1 + x_1, -y_1 + y_1) = (0, 0); \text{ hence } Z_4 = O.
\]

(vi) This was covered in 11.2.1.

(vii) For \( t_1 (O, Z_1) = (O, Z_2) \) where \( (x_2, y_2) = (t_1 x_1, t_1 y_1) \). Then

\[
t_2 \cdot (t_1 (O, Z_1)) = t_2 (O, Z_2) = (O, Z_3) \text{ where } (x_3, y_3) = (t_2 (t_1 x_1), t_2 (t_1 y_1)).
\]

Also \( (t_2 t_1) (O, Z_1) = (O, Z_4) \) where \( (x_4, y_4) = ((t_2 t_1) x_1, (t_2 t_1) y_1) \). Thus \( Z_3 = Z_4 \).

(viii) For \( (O, Z_1) + (O, Z_2) = (O, Z_3) \) and \( t \cdot [(O, Z_1) + (O, Z_2)] = t (O, Z_3) \) = \( (O, Z_4) \) where \( (x_3, y_3) = (x_1 + x_2, y_1 + y_2), (x_4, y_4) = (t (x_1 + x_2), t (y_1 + y_2)) \). Also

\[
t (O, Z_1) = (O, Z_5), t (O, Z_2) = (O, Z_6) \text{ where } (x_5, y_5) = (t x_1, t y_1),
\]

\[
(x_6, y_6) = (t x_2, t y_2). \text{ Moreover } (O, Z_5) + (O, Z_6) = (O, Z_7) \text{ where } (x_7, y_7) = (x_5 + x_6, y_5 + y_6) = (t x_1 + t x_2, t y_1 + t y_2). \text{ Hence } Z_4 = Z_7.
\]

(ix) For \( t_1 (O, Z_1) = (O, Z_2), t_2 (O, Z_1) = (O, Z_3), (t_1 + t_2) (O, Z_1) = (O, Z_4) \) and

\[
(O, Z_2) + (O, Z_3) = (O, Z_5) \text{ where } (x_2, y_2) = (t_1 x_1, t_1 y_1), (x_3, y_3) = (t_2 x_1, t_2 y_1) \text{ and } (x_4, y_4) = ((t_1 + t_2) x_1, (t_1 + t_2) y_1). \text{ Moreover } (x_5, y_5) = (x_2 + x_3, y_2 + y_3) = (t_1 x_1 + t_2 x_1, t_1 y_1 + t_2 y_1). \text{ Clearly } Z_4 = Z_5.
\]

(x) For \( 1 (O, Z_1) = (O, Z_2) \) where \( (x_2, y_2) = (1 x_1, 1 y_1) = (x_1, y_1). \text{ Thus } Z_2 = Z_1.\)
11.3 SCALAR OR DOT PRODUCTS

11.3.1

Definitions. We define a scalar product, or dot product, \((O, Z_1) \cdot (O, Z_2)\) as follows. If \(Z_1 = O\) then \((O, Z_1) \cdot (O, Z_2) = 0\); otherwise \(Z_1 \neq O\) and we set

\[
(O, Z_1) \cdot (O, Z_2) = \begin{cases} 
|O, Z_1| |O, \pi_{OZ_1}(Z_2)|, & \text{if } \pi_{OZ_1}(Z_2) \in [O, Z_1], \\
-|O, Z_1| |O, \pi_{OZ_1}(Z_2)|, & \text{if } \pi_{OZ_1}(Z_2) \in OZ_1 \setminus [O, Z_1].
\end{cases}
\]

Clearly the scalar product is a function on \(\mathcal{V}(\Pi; O) \times \mathcal{V}(\Pi; O)\) into \(\mathbb{R}\).

The norm \(\|a\|\) of a vector \(a = (O, Z)\) is defined to be the distance \(|O, Z|\).

The scalar product has the following properties:

(i) If \(Z_j = (x_j, y_j)\) for \(j = 1, 2\) then \(a \cdot b = (O, Z_1) \cdot (O, Z_2) = x_1x_2 + y_1y_2\).

(ii) For all \(a, b \in \mathcal{V}(\Pi; O)\), \(a \cdot b = b \cdot a\).

(iii) For all \(a, b, c \in \mathcal{V}(\Pi; O)\), \(a \cdot (b + c) = a \cdot b + a \cdot c\).

(iv) For all \(a, b \in \mathcal{V}(\Pi; O)\) and all \(t \in \mathbb{R}\), \(t \cdot (a \cdot b) = (t \cdot a) \cdot b\).

(v) For all \(a \neq O\), \(a \cdot a > 0\), while \(O \cdot O = 0\).

(vi) For all \(a\), \(|a| = \sqrt{a \cdot a}\).

Proof. (i) If \(Z_1 = O\), then \(x_1 = y_1 = 0\) so that \(x_1x_2 + y_1y_2 = 0\) as required.

Suppose then that \(Z_1 \neq O\). Write \(l = OZ_1\) and let \(m\) be the line through the point \(O\) which is perpendicular to \(l\). Define the closed half-plane \(\mathcal{H}_5 = \{X : \pi_l(X) \in [O, Z_1]\}\) and let \(\mathcal{H}_6\) be the other closed half-plane with edge \(m\). Now \(l \equiv -y_1x + x_1y = 0\) and \(m \equiv x_1x + y_1y = 0\).

Then as \(Z_1 \in \mathcal{H}_5\),

\[
\mathcal{H}_5 = \{Z \equiv (x, y) : x_1x + y_1y \geq 0\}, \quad \mathcal{H}_6 = \{Z \equiv (x, y) : x_1x + y_1y \leq 0\}.
\]

Figure 11.3.

Figure 11.4.
But by 6.6.1(ii),

\[ \pi_i(Z_2) \equiv \left( x_2 + \frac{y_1}{y_1^2 + x_1^2}(-y_1x_2 + x_1y_2), \ y_2 - \frac{x_1}{y_1^2 + x_1^2}(-y_1x_2 + x_1y_2) \right) \]

\[ = \left( x_1x_2 + \frac{y_1y_2}{x_1^2 + y_1^2}, \ y_1 \frac{x_1x_2 + y_1y_2}{x_1^2 + y_1^2} \right). \]

Thus

\[ |O, Z_1|^2|O, \pi_i(Z_2)|^2 = (x_1^2 + y_1^2) \left[ \left( \frac{x_1^2(x_1x_2 + y_1y_2)^2}{x_1^2 + y_1^2} \right)^2 + \left( \frac{y_1^2(x_1x_2 + y_1y_2)^2}{x_1^2 + y_1^2} \right)^2 \right] \]

\[ = (x_1x_2 + y_1y_2)^2, \]

so that \( |O, Z_1||O, \pi_i(Z_2)| = |x_1x_2 + y_1y_2| \).

If \( Z_2 \in \mathcal{H}_5 \) so that

\[ (O, Z_1). (O, Z_2) = |O, Z_1||O, \pi_i(Z_2)|, \]

and \( x_1x_2 + y_1y_2 \geq 0 \) so that \( |x_1x_2 + y_1y_2| = x_1x_2 + y_1y_2 \), clearly

\( (O, Z_1). (O, Z_2) = x_1x_2 + y_1y_2. \)

If \( Z_2 \in \mathcal{H}_6 \setminus m \) we have \( \pi_i(Z_2) \in l \setminus [O, Z_1] \). Then

\[ (O, Z_1). (O, Z_2) = -|O, Z_1||O, \pi_i(Z_2)| \]

and \( x_1x_2 + y_1y_2 \leq 0 \), so that \( |x_1x_2 + y_1y_2| = -(x_1x_2 + y_1y_2) \). Clearly again \( (O, Z_1). (O, Z_2) = x_1x_2 + y_1y_2. \)

(ii) Let \( a = (O, Z_1), \ b = (O, Z_2) \). Then by (i) of the present theorem, \( a \cdot b = x_1x_2 + y_1y_2 \), \( b \cdot a = x_2x_1 + y_2y_1 \), and clearly these are equal.

(iii) Let \( a = (O, Z_1), \ b = (O, Z_2), \ c = (O, Z_3) \). Then by 11.2.1(i) \( b + c = (O, Z_4) \) where \( Z_4 \equiv (x_2 + x_3, y_2 + y_3) \). Then by (i) above \( a \cdot (b + c) = x_1(x_2 + x_3) + y_1(y_2 + y_3) \), while \( a \cdot b + a \cdot c = (x_1x_2 + y_1y_2) + (x_1x_3 + y_1y_3) \), and these are equal.

(iv) Let \( a = (O, Z_1), \ b = (O, Z_2) \). Then \( a \cdot b = t(x_1 x_2 + y_1 y_2) \). But by 11.2.1(ii), \( t \cdot a = (O, Z_4) \) where \( Z_4 \equiv (tx_1, ty_1) \) and so \( t \cdot a \cdot b = (tx_1 x_2 + (ty_1) y_2) \), which is equal to the earlier expression.

(v) If \( a = (O, Z) \) then \( a \cdot a = x^2 + y^2 \). This is positive when \( (x, y) \neq (0, 0) \), and equal to 0 for \( x = y = 0 \).

(vi) This follows immediately.

**NOTE.** Note that 11.2.2(i) to (v) make \( \mathcal{V} \) a commutative group. In textbooks

on algebra it is proved that there is not a second element which has the property (iii); we shall refer to \( a \) as the null vector. It is also a standard result that for each \( a \in \mathcal{V} \) there is not a second element with the property (iv); we call \(-a\) the inverse of \( a \).

**Subtraction** — is defined by specifying the difference \( b - a = b + (-a) \); then \(-a\) is a binary operation on \( \mathcal{V} \). If \( a = (O, Z_1), \ b = (O, Z_2) \), then \( -a = (O, Z_3) \) where \( Z_3 \equiv (-x_1, -y_1) \), and consequently \( b - a = (O, Z_4) \) where \( Z_4 \equiv (x_2 - x_1, y_2 - y_1) \). Thus \( (O, Z_2) - (O, Z_1) = (O, Z_4) \) if and only if \( (Z_1, Z_2) \uparrow (O, Z_4) \).
**COMMENT.** Now that we have set up our couples we call \((O, Z)\) a **position vector** with respect to the point \(O\), and we adopt the standard notation \(\overrightarrow{OZ}\) for \((O, Z)\).

Position vectors can be used for many geometrical purposes instead of Cartesian coordinates, or complex coordinates and complex-valued distances. We would note that by 6.1.1(iv) and 11.2 \(Z_0 = m p(Z_1, Z_2)\) if and only if \(\overrightarrow{OZ_0} = \frac{1}{2}(\overrightarrow{OZ_1} + \overrightarrow{OZ_2})\); by 10.1.1(v) that \(Z_1 Z_2 \parallel Z_3 Z_4\) if and only if \(\overrightarrow{OZ_4} - \overrightarrow{OZ_3} = t(\overrightarrow{OZ_2} - \overrightarrow{OZ_1})\) for some \(t \neq 0\) in \(\mathbb{R}\), and by 9.7.1(ii) and 6.5.1 Corollary (ii) that \(Z_1 Z_2 \perp Z_3 Z_4\) if and only if \((\overrightarrow{OZ_1} - \overrightarrow{OZ_2}).(\overrightarrow{OZ_3} - \overrightarrow{OZ_4}) = 0\). Most importantly, from parametric equations of a line \(x = x_1 + t(x_2 - x_1), y = y_1 + t(y_2 - y_1)\) \((t \in \mathbb{R})\), we have that \(Z \in Z_1 Z_2\) if and only if

\[
\overrightarrow{OZ} = \overrightarrow{OZ_1} + t(\overrightarrow{OZ_2} - \overrightarrow{OZ_1}) = (1 - t)\overrightarrow{OZ_1} + t\overrightarrow{OZ_2}
\]

(11.3.1)

for some \(t \in \mathbb{R}\).

**COMMENT.** It is usual, in modern treatments, to define vectors to be the equivalence classes for equipollence. This defines free vectors. Position vectors are then defined by taking a specific point \(O\) in \(\Pi\) so that we have a pointed plane, and then concentrating on the representatives of the form \((O, Z)\) for the vectors. But if our objective is to introduce position vectors, it is wasteful of effort to set up the free vectors, and in fact the use of free vectors and subsequent specialisation to position vectors can be a confusing route to position vectors.

### 11.4 COMPONENTS OF A VECTOR

#### 11.4.1 Components

Given non-collinear points \(Z_1, Z_2, Z_3\), we wish to obtain an expression

\[
\overrightarrow{Z_1 Z} = p\overrightarrow{Z_1 Z_2} + q\overrightarrow{Z_1 Z_3}.
\]

For this we need

\[
(x_2 - x_1)p + (x_3 - x_1)q = x - x_1, \\
(y_2 - y_1)p + (y_3 - y_1)q = y - y_1.
\]

We obtain the solutions

\[
p = \frac{\delta\mathcal{F}(Z_1, Z, Z_3)}{\delta\mathcal{F}(Z_1, Z_2, Z_3)}, \quad q = \frac{\delta\mathcal{F}(Z_1, Z_2, Z)}{\delta\mathcal{F}(Z_1, Z_2, Z_3)},
\]

and so have

\[
\overrightarrow{Z_1 Z} = \frac{\delta\mathcal{F}(Z_1, Z, Z_3)}{\delta\mathcal{F}(Z_1, Z_2, Z_3)}\overrightarrow{Z_1 Z_2} + \frac{\delta\mathcal{F}(Z_1, Z_2, Z)}{\delta\mathcal{F}(Z_1, Z_2, Z_3)}\overrightarrow{Z_1 Z_3}.
\]
11.4.2 Areal coordinates

Given non-collinear points $Z_1, Z_2, Z_3$, the position vector of any point $Z$ of the plane can be expressed in the form $\overrightarrow{OZ} = p\overrightarrow{OZ_1} + q\overrightarrow{OZ_2} + r\overrightarrow{OZ_3}$, with $p + q + r = 1$. This is equivalent to having $q, r$ such that

\[ q(x_2 - x_1) + r(x_3 - x_1) = x - x_1, \]
\[ q(y_2 - y_1) + r(y_3 - y_1) = y - y_1. \]

These equations have the unique solution

\[ q = \frac{\delta_{\mathcal{F}}(Z, Z_3, Z_1)}{\delta_{\mathcal{F}}(Z_1, Z_2, Z_3)}, \quad r = \frac{\delta_{\mathcal{F}}(Z, Z_1, Z_2)}{\delta_{\mathcal{F}}(Z_1, Z_2, Z_3)}, \]

and now we take $p = 1 - q - r$ so that by 10.5.4

\[ p = \frac{\delta_{\mathcal{F}}(Z, Z_2, Z_3)}{\delta_{\mathcal{F}}(Z_1, Z_2, Z_3)}. \]

For non-collinear points $Z_1, Z_2, Z_3$, for any $Z$ we write

\[ \alpha = \delta_{\mathcal{F}}(Z, Z_2, Z_3), \quad \beta = \delta_{\mathcal{F}}(Z, Z_3, Z_1), \quad \gamma = \delta_{\mathcal{F}}(Z, Z_1, Z_2), \]

and call $(\alpha, \beta, \gamma)$ areal point coordinates of $Z$ with respect to $(Z_1, Z_2, Z_3)$. Note that we have

\[ p = \frac{\alpha}{\delta_{\mathcal{F}}(Z_1, Z_2, Z_3)}, \quad q = \frac{\beta}{\delta_{\mathcal{F}}(Z_1, Z_2, Z_3)}, \quad r = \frac{\gamma}{\delta_{\mathcal{F}}(Z_1, Z_2, Z_3)}, \]

and $\alpha + \beta + \gamma = \delta_{\mathcal{F}}(Z_1, Z_2, Z_3)$. These were first used by Möbius in 1827.

11.4.3 Cartesian coordinates from areal coordinates

With the notation in 11.4.2, we have

\[ (y_2 - y_3)x - (x_2 - x_3)y = 2\alpha - x_2y_3 + x_3y_2, \]
\[ (y_3 - y_1)x - (x_3 - x_1)y = 2\beta - x_3y_1 + x_1y_3, \]

and if we solve these we obtain

\[ x = \frac{x_1\alpha + x_2\beta + x_3\gamma}{\delta_{\mathcal{F}}(Z_1, Z_2, Z_3)}, \quad y = \frac{y_1\alpha + y_2\beta + y_3\gamma}{\delta_{\mathcal{F}}(Z_1, Z_2, Z_3)}. \]

11.4.4

The representation in 11.4.2 is in fact independent of the origin $O$. For we have

\[ x = px_1 + qx_2 + rx_3, \quad y = py_1 + qy_2 + ry_3, \]
and so for any point \( Z_0 \equiv \mathscr{F} (x_0, y_0) \),

\[
\begin{align*}
  x - x_0 &= p(x_1 - x_0) + q(x_2 - x_0) + r(x_3 - x_0), \\
  y - y_0 &= p(y_1 - y_0) + q(y_2 - y_0) + r(y_3 - y_0).
\end{align*}
\]

But \( Z \equiv \mathscr{F}' (x - x_0, y - y_0) \), where \( \mathscr{F}' = t_{OZ_0} (\mathscr{F}) \). Hence \( \overrightarrow{Z_0Z} = p\overrightarrow{Z_0Z_1} + q\overrightarrow{Z_0Z_2} + r\overrightarrow{Z_0Z_3} \), with \( p + q + r = 1 \).

**NOTATION.** Where a vector equation is independent of the origin, as in \( \overrightarrow{OZ} = p\overrightarrow{OZ_1} + q\overrightarrow{OZ_2} + r\overrightarrow{OZ_3} \), with \( p + q + r = 1 \), it is convenient to write this as \( Z = pZ_1 + qZ_2 + rZ_3 \) with \( p + q + r = 1 \). In particular, in (11.3.1) we write \( Z = (1 - t)Z_1 + tZ_2 \).

Figure 11.5.

Figure 11.5 caters for when \( O \) and \( Z_1 \) are taken as origins, a similar diagram would cater for when \( Z_0 \) and \( Z_1 \) are origins, and then a combination of the two would give the stated result.

11.4.5

We also use the notation \( \delta_{\mathscr{F}} (Z_1, Z_2, pZ_4 + qZ_5 + rZ_6) \) for \( \delta_{\mathscr{F}} (Z_1, Z_2, Z_3) \) where \( \overrightarrow{OZ_3} = p\overrightarrow{OZ_4} + q\overrightarrow{OZ_5} + r\overrightarrow{OZ_6} \) and \( p + q + r = 1 \). We can then write the conclusion of 10.5.3 as

\[
\delta_{\mathscr{F}} (Z_1, Z_2, (1 - s)Z_4 + sZ_5) = (1 - s)\delta_{\mathscr{F}} (Z_1, Z_2, Z_4) + s\delta_{\mathscr{F}} (Z_1, Z_2, Z_5).
\]

The more general result

\[
\begin{align*}
  \delta_{\mathscr{F}} (Z_1, Z_2, pZ_4 + qZ_5 + rZ_6) \\
  &= p\delta_{\mathscr{F}} (Z_1, Z_2, Z_4) + q\delta_{\mathscr{F}} (Z_1, Z_2, Z_5) + r\delta_{\mathscr{F}} (Z_1, Z_2, Z_6),
\end{align*}
\]
where \( p + q + r = 1 \), can be deduced from this. For

\[
\delta_{\mathcal{P}}(Z_1, Z_2, pZ_4 + qZ_5 + rZ_6)
= \delta_{\mathcal{P}} \left( Z_1, Z_2, pZ_4 + (1 - p) \left( \frac{q}{1 - p}Z_5 + \frac{r}{1 - p}Z_6 \right) \right)
= p\delta_{\mathcal{P}}(Z_1, Z_2, Z_4) + (1 - p)\delta_{\mathcal{P}} \left( Z_1, Z_2, \frac{q}{1 - p}Z_5 + \frac{r}{1 - p}Z_6 \right)
= p\delta_{\mathcal{P}}(Z_1, Z_2, Z_4) + (1 - p) \left[ \frac{q}{1 - p} \delta_{\mathcal{P}}(Z_1, Z_2, Z_5) + \frac{r}{1 - p} \delta_{\mathcal{P}}(Z_1, Z_2, Z_6) \right].
\]

In this we have used the fact that

\[
\frac{q}{1 - p} + \frac{r}{1 - p} = \frac{q + r}{1 - p} = \frac{1 - p}{1 - p} = 1.
\]

### 11.5 VECTOR METHODS IN GEOMETRY

There is an informative account of many of the results of this chapter contained in Coxeter and Greitzer [5], dealt with by the methods of pure geometry.

Some results are very basic, involving just collinearities or concurrences, or ratio results. We start by showing how vector notation can be used to prove such results in a very straightforward fashion.

#### 11.5.1 Menelaus’ theorem, c. 100 A.D.

On using the notation of sensed distances and sensed ratios in 7.6.1, we note that for non-collinear points \( Z_1, Z_2 \) and \( Z_3 \), let \( Z_4 \in Z_2Z_3 \), \( Z_5 \in Z_3Z_1 \) and \( Z_6 \in Z_1Z_2 \). Then \( Z_4, Z_5 \) and \( Z_6 \) are collinear if and only if

\[
\frac{Z_2Z_4}{Z_4Z_3} \frac{Z_3Z_5}{Z_5Z_1} \frac{Z_1Z_6}{Z_6Z_2} = -1.
\]

**Proof.** Let \( Z_4 = (1 - r)Z_2 + rZ_3 \), \( Z_5 = (1 - s)Z_3 + sZ_1 \), \( Z_6 = (1 - t)Z_1 + tZ_2 \).

Since \( Z_4, Z_5 \) and \( Z_6 \) are collinear, we have that \( Z_6 = (1 - u)Z_4 + uZ_5 \), for some real number \( u \). Then

\[
(1 - t)Z_1 + tZ_2 = (1 - u)[(1 - r)Z_2 + rZ_3] + u[(1 - s)Z_3 + sZ_1].
\]
As the coefficients on each side add to 1, by the uniqueness in 11.4.2 we can equate coefficients and thus obtain

\[1 - t = su, \quad t = (1 - u)(1 - r), \quad r(1 - u) = -u(1 - s)\]

On eliminating \(u\) we obtain

\[
\frac{r}{1 - r} \frac{s}{1 - s} \frac{t}{1 - t} = -\frac{u}{1 - u} \frac{1}{1 - u} (1 - u) = -1,
\]

and so

\[
\frac{r}{1 - r} \frac{s}{1 - s} \frac{t}{1 - t} = -1.
\]

This yields the stated result. This is known as Menelaus’ theorem.

11.5.2 Ceva’s theorem and converse, 1678 A.D.

For non-collinear points \(Z_1, Z_2\) and \(Z_3\), let \(Z_4 \in Z_2Z_3\), \(Z_5 \in Z_3Z_1\) and \(Z_6 \in Z_1Z_2\). If \(Z_1Z_4, Z_2Z_5\) and \(Z_3Z_6\) are concurrent, then

\[
\frac{Z_2Z_4}{Z_4Z_3} \frac{Z_3Z_5}{Z_5Z_1} \frac{Z_1Z_6}{Z_6Z_2} = 1. \tag{11.5.1}
\]

**Proof.** Denoting the point of concurrency by \(Z_0\), we have

\[
Z_4 = (1 - u)Z_0 + uZ_1 = (1 - r)Z_2 + rZ_3,
\]

\[
Z_5 = (1 - v)Z_0 + vZ_2 = (1 - s)Z_3 + sZ_1,
\]

\[
Z_6 = (1 - w)Z_0 + wZ_3 = (1 - t)Z_1 + tZ_2,
\]

for some \(u, v, w, r, s, t \in \mathbb{R}\). Then

\[
Z_0 = -\frac{u}{1 - u} Z_1 + \frac{1 - r}{1 - u} Z_2 + \frac{r}{1 - u} Z_3,
\]

\[
Z_0 = \frac{s}{1 - v} Z_1 - \frac{v}{1 - v} Z_2 + \frac{1 - s}{1 - v} Z_3,
\]

\[
Z_0 = \frac{1 - t}{1 - w} Z_1 + \frac{t}{1 - w} Z_2 - \frac{w}{1 - w} Z_3.
\]

On equating the coefficients of \(Z_1, Z_2\) and \(Z_3\), in turn, we obtain

\[
\frac{u}{1 - u} = \frac{s}{1 - v} = \frac{1 - t}{1 - w}, \quad \frac{1 - r}{1 - u} = -\frac{v}{1 - v} = \frac{t}{1 - w}, \quad \frac{r}{1 - u} = \frac{1 - s}{1 - v} = -\frac{w}{1 - w}.
\]

![Figure 11.7](image-url)
From this
\[
\frac{s}{1-t} = \frac{1-v}{1-w}, \quad \frac{t}{1-r} = \frac{1-w}{1-u}, \quad \frac{r}{1-s} = \frac{1-u}{1-v},
\]
and so by multiplication
\[
\frac{s}{1-t} \frac{t}{1-r} \frac{r}{1-s} = 1.
\]
Thus we obtain our conclusion. This is known as **Ceva’s theorem**.

In fact we also have that
\[
\frac{u}{s} = -\frac{1-u}{1-v}, \quad \frac{v}{t} = -\frac{1-v}{1-w}, \quad \frac{w}{r} = -\frac{1-w}{1-u},
\]
which gives $uvw = -rst$. This is
\[
\begin{align*}
Z_0Z_4 &= Z_0Z_5 - Z_0Z_6, \\
Z_0Z_1 &= Z_0Z_2 - Z_0Z_3.
\end{align*}
\]
**CONVERSE** of Ceva’s theorem. Conversely, for non-collinear points $Z_1, Z_2$ and $Z_3$, let $Z_4 \in Z_2Z_3$, $Z_5 \in Z_3Z_1$ and $Z_6 \in Z_1Z_2$. If (11.5.1) holds and $Z_2Z_5$ and $Z_3Z_6$ meet at a point $Z_0$, then $Z_1Z_4$ also passes through $Z_0$.

To start our proof we note that we have
\[
\begin{align*}
Z_5 &= (1-v)Z_0 + vZ_2 = (1-s)Z_3 + sZ_1, \\
Z_6 &= (1-w)Z_0 + wZ_3 = (1-t)Z_1 + tZ_2.
\end{align*}
\]
Hence
\[
Z_0 = \frac{s}{1-v}Z_1 - \frac{v}{1-v}Z_2 + \frac{1-s}{1-v}Z_3, \quad Z_0 = \frac{1-t}{1-w}Z_1 + \frac{t}{1-w}Z_2 - \frac{w}{1-w}Z_3.
\]
It follows that
\[
\begin{align*}
\frac{s}{1-v} &= \frac{1-t}{1-w}, \quad \frac{v}{1-v} = \frac{1-s}{1-w}, \quad \frac{1-s}{1-v} = -\frac{w}{1-w},
\end{align*}
\]
from which
\[
\frac{s}{1-t} = \frac{1-v}{1-w}, \quad (1-s)t = vw.
\]
On eliminating $s$ between these, we obtain $(1-v)t^2 + (v-w)t - vw(1-w) = 0$. We then obtain two pairs of solutions, $t = w, s = 1-v$, and
\[
\begin{align*}
t &= -\frac{1-w}{1-v}, \quad s = \frac{1-vw}{1-w}.
\end{align*}
\]
The first pair of solutions leads to $v = w = 0$ and so $Z_5 = Z_6 = Z_0 = Z_1$, which we regard as a degenerate case.

With $Z_4 = (1-r)Z_2 + rZ_3$, we are given that
\[
\frac{1-r}{r} = \frac{st}{(1-s)(1-t)},
\]
and so have

$$Z_4 = \frac{st}{st + (1-s)(1-t)} Z_2 + \frac{(1-s)(1-t)}{st + (1-s)(1-t)} Z_3.$$  

With the second pair of solutions above, we obtain that

$$Z_0 = \frac{1-vw}{(1-v)(1-w)} Z_1 - \frac{v(1-w)}{(1-v)(1-w)} Z_2 + \frac{w(1-v)}{(1-v)(1-w)} Z_3,$$

and also that

$$Z_4 = \frac{v(1-w)}{v + w - 2vw} Z_2 + \frac{w(1-v)}{v + w - 2vw} Z_3,$$

so that

$$Z_0 = \frac{1-vw}{(1-v)(1-w)} Z_1 - \frac{v + w - 2vw}{(1-v)(1-w)} Z_4.$$  

As the sum of the coefficients of $Z_1$ and $Z_4$ is equal to 1, $Z_1 Z_4$ passes through $Z_0$. This proves the result.

To obtain a formula for $Z_0$ we note that on solving the second pair of solutions above for $v$ and $w$, we obtain the pair of solutions

$$v = 1, w = 1; \quad v = -\frac{st}{1-t}, w = -\frac{(1-s)(1-t)}{s}.$$  

To see this, note that

$$1 - w = -\frac{1-v}{v} t, \quad w = 1 + \frac{1-v}{v} t,$$

so that

$$1 - v \frac{1 + \frac{1-v}{v} t}{\frac{1-v}{v} t} = s, \quad \text{i.e.} \quad 1 - v - \frac{(1-v)t}{\frac{1-v}{v} t} = s.$$  

Thus either $v = 1$ and consequently $w = 1$, or

$$\frac{1-t}{-\frac{1}{v} t} = s, \quad \text{i.e.} \quad v = \frac{st}{1-t},$$

and hence

$$w = -\frac{(1-s)(1-t)}{s}.$$  

The first pair lead to $Z_5 = Z_2, Z_6 = Z_3$, another degenerate case, while the second pair lead to

$$Z_0 = \frac{s(1-t)}{1-t + st} Z_1 + \frac{st}{1-t + st} Z_2 + \frac{(1-s)(1-t)}{1-t + st} Z_3.$$  

(11.5.2)

Because of the condition (11.5.1) the coefficients in (11.5.2) could be given in several different forms.
11.5.3 Desargues’ perspective theorem, 1648 A.D.

Let \((Z_1, Z_2, Z_3)\) and \((Z_4, Z_5, Z_6)\) be two pairs of non-collinear points. Let \(Z_2Z_3\) and \(Z_5Z_6\) meet at \(W_1\), \(Z_3Z_4\) and \(Z_6Z_4\) meet at \(W_2\), and \(Z_1Z_2\) and \(Z_4Z_5\) meet at \(W_3\). Then \(W_1, W_2, W_3\) are collinear if and only if \(Z_1Z_4, Z_2Z_5, Z_3Z_6\) are concurrent.

**Proof.** Suppose that \(Z_1Z_4, Z_2Z_5, Z_3Z_6\) meet at a point \(Z_0\). Then

\[
Z_4 = (1 - u)Z_0 + uZ_1,
\]

\[
Z_5 = (1 - v)Z_0 + vZ_2,
\]

\[
Z_6 = (1 - w)Z_0 + wZ_3,
\]

for some \(u, v, w \in \mathbb{R}\).

On eliminating \(Z_0\) between the second and third of these, we obtain that

\[
(1 - w)Z_5 - (1 - v)Z_6 = v(1 - w)Z_2 - w(1 - v)Z_3,
\]

from which we obtain that

\[
\frac{1 - w}{v - w}Z_5 - \frac{1 - v}{v - w}Z_6 = \frac{v(1 - w)}{v - w}Z_2 - \frac{w(1 - v)}{v - w}Z_3.
\]

Now the sum of the coefficients of \(Z_5\) and \(Z_6\) is equal to 1, so the left-hand side represents a point on the line \(Z_5Z_6\). Similarly, the sum of the coefficients of \(Z_2\) and \(Z_3\) is equal to 1, so the right-hand side represents a point on the line \(Z_2Z_3\). Thus this must be the point \(W_1\).

By a similar argument based on the third and first lines, we find that

\[
\frac{1 - u}{w - u}Z_6 - \frac{1 - w}{w - u}Z_4 = \frac{w(1 - u)}{w - u}Z_3 - \frac{u(1 - w)}{w - u}Z_1
\]

must be the point \(W_2\), and by a similar argument based on the first and second lines, we find that

\[
\frac{1 - v}{u - v}Z_4 - \frac{1 - u}{u - v}Z_5 = \frac{u(1 - v)}{u - v}Z_1 - \frac{v(1 - u)}{u - v}Z_2
\]

must be the point \(W_3\).
Then by repeated use of 10.5.3 and 11.4.5

\[
\delta_{\mathcal{F}}(W_1, W_2, W_3) = \delta_{\mathcal{F}} \left( \frac{v(1-w)}{v-w} Z_2 - \frac{w(1-v)}{v-w} Z_3, -\frac{u(1-w)}{w-u} Z_1 + \frac{w(1-u)}{w-u} Z_3, \right)
\]

\[
\frac{u(1-v)}{u-v} Z_1 - \frac{v(1-u)}{u-v} Z_2
\]

\[
= \left[ \frac{v(1-w)}{v-w} \frac{w(1-u)}{u-v} Z_3 - \frac{w(1-v)}{v-w} - \frac{u(1-w)}{u-v} - \frac{v(1-u)}{u-v} \right] \delta_{\mathcal{F}}(Z_1, Z_2, Z_3)
\]

\[
= 0.
\]

This shows that \(W_1, W_2\) and \(W_3\) are collinear.

This is known as Desargues' perspective or two-triangle theorem.

Conversely, let

\[
W_1 = (1-l)Z_2 + lZ_3 = (1-m)Z_5 + mZ_6,
\]

\[
W_2 = (1-p)Z_3 + pZ_4 = (1-q)Z_6 + qZ_4,
\]

\[
W_3 = (1-r)Z_1 + rZ_2 = (1-s)Z_4 + sZ_5.
\]

From the third of these we deduce that \((1-r)Z_1 - (1-s)Z_4 = sZ_5 - rZ_2\), and from this

\[
\frac{1-r}{s-r} Z_1 - \frac{1-s}{s-r} Z_4 = \frac{s}{s-r} Z_5 - \frac{r}{s-r} Z_2,
\]

so that this must be the point of intersection of \(Z_1Z_4\) and \(Z_2Z_5\).

By a similar argument, we deduce from the second equation that

\[
\frac{1-l}{m-l} Z_2 - \frac{1-m}{m-l} Z_5 = \frac{m}{m-l} Z_6 - \frac{l}{m-l} Z_3,
\]

and so this must be the point of intersection of \(Z_2Z_5\) and \(Z_3Z_6\). By a similar argument, we deduce from the first equation that

\[
\frac{1-p}{q-p} Z_3 - \frac{1-p}{q-p} Z_6 = \frac{q}{q-p} Z_4 - \frac{p}{q-p} Z_1,
\]

and so this must be the point of intersection of \(Z_3Z_6\) and \(Z_1Z_4\).

We are given now that \(W_1, W_2\) and \(W_3\) are collinear, so that \(W_3 = (1-t)W_1 + tW_2\), for some \(t \in \mathbb{R}\). Then

\[
(1-t)[(1-l)Z_2 + lZ_3] + t[(1-p)Z_3 + pZ_1] = (1-r)Z_1 + rZ_2,
\]

\[
(1-t)[(1-m)Z_5 + mZ_6] + t[(1-q)Z_6 + qZ_4] = (1-s)Z_4 + sZ_5.
\]

Since the points \(Z_1, Z_2, Z_3\) are not collinear we can equate the coefficients in the first line here, and obtain that

\[
pt = 1 - r, \quad (1-t)(1-l) = r, \quad (1-t)l + t(1-p) = 0,
\]
and since the points $Z_4, Z_5, Z_6$ are not collinear we can equate the coefficients in the second line, and obtain that

$$qt = 1 - s, \ (1 - r)(1 - m) = s, \ (1 - r)m + t(1 - q) = 0.$$  

Now for $Z_2Z_5$ and $Z_3Z_6$ to meet $Z_1Z_4$ in the same point, we need to have

$$\frac{1 - r}{s - r} = -\frac{p}{q - p},$$

and from this

$$\frac{1 - r}{p} = -\frac{s - r}{q - p}.$$  

But we have from above

$$\frac{1 - r}{p} = \frac{1 - s}{q},$$

as a common value of $t$, and so need

$$\frac{1 - s}{q} = -\frac{s - r}{q - p}$$

or equivalently $q(1 - r) = p(1 - s)$, and we have already noted that this is so.

It follows that $Z_1Z_4, Z_2Z_5$ and $Z_3Z_6$ are concurrent.

11.5.4 Pappus’ theorem, c. 300A.D.

Let the points $Z_1, Z_2, Z_3$ lie on one line, and the points $Z_4, Z_5, Z_6$ lie on a second line, these two lines intersecting at some point $Z_0$. Suppose that $Z_2Z_6$ and $Z_3Z_3$ meet at $W_1$, $Z_3Z_4$ and $Z_6Z_1$ meet at $W_2$, and $Z_1Z_5$ and $Z_4Z_2$ meet at $W_3$. Then the points $W_1, W_2, W_3$ are collinear.

**Proof.** We have that

$$Z_2 = (1 - p)Z_0 + pZ_1, \ Z_3 = (1 - q)Z_0 + qZ_1,$$

$$Z_5 = (1 - u)Z_0 + uZ_4, \ Z_6 = (1 - v)Z_0 + vZ_4,$$

for some $p, q, u, v \in \mathbb{R}$. On eliminating $Z_0$ from the equations for $Z_2$ and $Z_5$, we find that

$$(1 - u)Z_2 - (1 - p)Z_5 = p(1 - u)Z_4 - u(1 - p)Z_4,$$

and so

$$\frac{1 - u}{1 - pu}Z_2 + \frac{u(1 - p)}{1 - pu}Z_4 = \frac{p(1 - u)}{1 - pu}Z_1 + \frac{1 - p}{1 - pu}Z_5.$$
This must be the point $W_3$ then. Similarly, on eliminating $Z_0$ from the equations for $Z_3$ and $Z_6$ we have that

$$(1-v)Z_3 - (1-q)Z_6 = q(1-v)Z_4 - (1-q)vZ_4,$$

and so

$$\frac{1-v}{1-qv}Z_3 + \frac{(1-q)v}{1-qv}Z_4 = \frac{q(1-v)}{1-qv}Z_1 + \frac{1-q}{1-qv}Z_6.$$ 

This must be the point $W_2$ then.

Now from the equations for $Z_2$ and $Z_3$ we have that $pZ_3 - qZ_2 = (p-q)Z_0$, and from the equations for $Z_5$ and $Z_6$ we have that $uZ_6 - vZ_5 = (u-v)Z_0$. On combining these, we have that

$$(v-u)(pZ_3 - qZ_2) = (q-p)(uZ_6 - vZ_5).$$

From this we have that

$$\frac{u(q-p)}{qv-pu}Z_6 + \frac{q(v-u)}{qv-pu}Z_2 = \frac{p(v-u)}{qv-pu}Z_3 + \frac{(q-p)v}{qv-pu}Z_5.$$ 

This must then be the point $W_1$.

However, the left-hand sides of the representations for $W_1, W_2$ and $W_3$ contain four points $Z_1, Z_2, Z_5, Z_6$ and we wish to reduce this to three non-collinear points. For this purpose we eliminate $Z_5$. From the equations for $Z_5$ and $Z_6$ we have that $uZ_6 - vZ_5 = (u-v)Z_0$, while from the equation for $Z_2$ we have $Z_2 - pZ_1 = (1-p)Z_0$. Combining these gives

$$Z_5 = \frac{u}{v}Z_6 - \frac{(u-v)}{v(1-p)}(Z_2 - pZ_1).$$

On substitution, this gives that

$$W_3 = \frac{pu(1-v)}{v(1-pu)}Z_1 + \frac{v-u}{v(1-pu)}Z_2 + \frac{u(1-p)}{v(1-pu)}Z_6.$$

We note that the sum of the coefficients for each of $W_1, W_2, W_3$ in terms of $Z_1, Z_2$ and $Z_6$ is equal to 1, and so by repeated use of 10.5.3 and 11.4.5 we have that
\[ \delta_{\mathcal{F}}(W_1, W_2, W_3) \text{ is equal to} \]
\[ \frac{q(v-u)}{qv-pu} Z_2 + \frac{u(q-p)}{qv-pu} Z_6, \quad \frac{q(1-v)}{1-qv} Z_1 + \frac{1-q}{1-qv} Z_6, \]
\[ \frac{pu(1-v)}{v(1-pu)} Z_1 + \frac{v-u}{v(1-pu)} Z_2 + \frac{u(1-p)}{v(1-pu)} Z_6 \]
\[ = \frac{q(v-u)}{qv-pu} \frac{q(1-v)}{1-qv} \frac{u(1-p)}{v(1-pu)} \delta_{\mathcal{F}}(Z_2, Z_1, Z_6) \]
\[ + \frac{q(v-u)(1-q)}{qv-pu} \frac{pu(1-v)}{1-qv} \frac{v-u}{v(1-pu)} \delta_{\mathcal{F}}(Z_2, Z_6, Z_1) \]
\[ + \frac{u(q-p)}{qv-pu} \frac{q(1-v)}{1-qv} \frac{v-u}{v(1-pu)} \delta_{\mathcal{F}}(Z_6, Z_1, Z_2) \]
\[ = \frac{qu(1-v)(v-u)}{v(qv-pu)(1-qv)((1-pu)^{-1}q(1-p) + p(1-q) + q-p) \delta_{\mathcal{F}}(Z_1, Z_2, Z_6) \]
\[ = 0. \]

This shows that \( W_1, W_2 \) and \( W_3 \) are collinear. This is known as **Pappus’ theorem**.

### 11.5.5 Centroid of a triangle

If \( Z_4, Z_5, Z_6 \) are the mid-points of \( \{Z_2, Z_3\}, \{Z_3, Z_1\}, \{Z_1, Z_2\} \), respectively, then with the notation of 11.5.2 we have that \( r = s = t = \frac{1}{2} \), and the condition (11.5.1) in the converse of Ceva’s theorem holds. Note that \( [Z_3, Z_6] \) is a cross-bar for the interior region \( \mathcal{F}(Z_3 Z_2 Z_1) \) and so \( [Z_2, Z_5] \) meets \( [Z_3, Z_6] \) in a point \( Z_7 \), which is thus on both \( Z_2 Z_5 \) and \( Z_3 Z_6 \). It follows that it is also on \( Z_1 Z_4 \). Thus the lines joining the vertices of a triangle to the mid-points of the opposite sides are concurrent. The point of concurrence \( Z_7 \) is called the **centroid** of the triangle, and for it by 11.5.2 we have
\[ Z_7 = \frac{1}{3} Z_1 + \frac{1}{3} Z_2 + \frac{1}{3} Z_3. \quad (11.5.3) \]

### 11.5.6 Orthocentre of a triangle

Let \( Z_8, Z_9, Z_{10} \) be the feet of the perpendiculars from \( Z_1 \) to \( Z_2 Z_3 \), \( Z_2 \) to \( Z_3 Z_1 \), \( Z_3 \) to \( Z_1 Z_2 \), respectively. Then with the notation of 11.5.2 we have that
\[ r = \frac{c}{a} \cos \beta, \quad s = \frac{a}{b} \cos \gamma, \quad t = \frac{b}{c} \cos \alpha. \]

Hence
\[ 1 - r = \frac{a - c \cos \beta}{a} = \frac{c \cos \beta + b \cos \gamma - c \cos \beta}{a} = \frac{b}{a} \cos \gamma. \]

Similarly
\[ 1 - s = \frac{c}{b} \cos \alpha, \quad 1 - t = \frac{a}{c} \cos \beta. \]

It follows that the condition (11.5.1) in the converse of Ceva’s theorem is true.
Repeating an argument that we used in 7.2.3, suppose now that \( m \) and \( n \) are any lines which are perpendicular to \( Z_3Z_1 \) and \( Z_1Z_2 \), respectively. If we had \( m \parallel n \), then we would have \( m \perp Z_3Z_1, n \parallel m \) so that \( n \perp Z_3Z_1 \); but already \( n \perp Z_1Z_2 \) so \( Z_3Z_1 \parallel Z_1Z_2 \); as \( Z_1, Z_2, Z_3 \) are not collinear, this gives a contradiction.

Thus \( m \) is not parallel to \( n \) and so these lines meet in a unique point \( Z_{11} \). In particular the lines \( Z_2Z_9, Z_3Z_{10} \) must meet in a unique point \( Z_{11} \) and then by the converse of Ceva’s theorem, \( Z_1Z_4 \) will pass through \( Z_{11} \). Thus the lines through the vertices of a triangle which are perpendicular to the opposite side-lines are concurrent. The point of concurrence \( Z_{11} \) is called the orthocentre of the triangle.

By (11.5.2) we thus have

\[
Z_{11} = \frac{a \cos \gamma}{b \cos \beta + c \cos \gamma} Z_1 + \frac{c \cos \alpha}{a \cos \beta + b \cos \gamma} Z_2 + \frac{a \cos \beta}{b \cos \alpha + c \cos \gamma} Z_3.
\]

We could also proceed in this special case as follows. The argument is laid out for the case in the diagram, with \( \beta \) and \( \gamma \) acute angles and \((Z_1, Z_2, Z_3)\) positive in orientation. The other cases can be treated similarly.

Now by 5.2.2 applied to \([Z_{10}, Z_2, Z_3]\), \( |\angle Z_{11}Z_2Z_4| = |\angle Z_{10}Z_2Z_3| = 90 - |\gamma| \) so that

\[
\frac{|Z_{11}, Z_8|}{|Z_2, Z_8|} = \tan \angle Z_{11}Z_2Z_8 = \cot \gamma.
\]

But \( |Z_2, Z_8| = c \cos \beta \) and so \( |Z_{11}, Z_8| = c \cos \beta \cot \gamma \). Thus \( \delta_{\mathcal{F}}(Z_{11}, Z_2, Z_3) = \frac{1}{2} ac \cos \beta \cot \gamma \) and since \( \delta_{\mathcal{F}}(Z_1, Z_2, Z_3) = \frac{1}{2} ac \sin \beta \), we have that

\[
\frac{\delta_{\mathcal{F}}(Z_{11}, Z_2, Z_3)}{\delta_{\mathcal{F}}(Z_1, Z_2, Z_3)} = \cot \beta \cot \gamma.
\]

As similar results hold in the other two cases, we have by 11.4.2 that

\[
Z_{11} = \cot \beta \cot \gamma Z_1 + \cot \gamma \cot \alpha Z_2 + \cot \alpha \cot \beta Z_3.
\]

That the sum of the coefficients is equal to 1 follows from the identity

\[
\tan \alpha + \tan \beta + \tan \gamma = \tan \alpha \tan \beta \tan \gamma
\]
for the angles of a triangle. For, using the notation of 10.8.1, $|\alpha|^\circ + |\beta|^\circ + |\gamma|^\circ = 180$, and so $\alpha + \beta + \gamma = 180$ so that
\[
-\tan \gamma = \tan(180 - \gamma) = \tan(\alpha + \beta)
\]
\[
= \frac{\tan \alpha + \tan \beta}{1 - \tan \alpha \tan \beta},
\]
whence the result follows by multiplying across and rearranging. This formula fails in the case of a right-angled triangle.

From our two methods we have two formulae for $Z_{11}$, but we further note that
\[
\cos(\alpha + \gamma) = \cos(180 - \beta),
\]
\[
\cos \alpha \cos \gamma - \sin \alpha \sin \gamma = -\cos \beta,
\]
\[
\cos \alpha \cos \gamma + \cos \beta = \sin \alpha \sin \gamma.
\]

On using this with the sine rule, the two formulae for the orthocentre are reconciled.

### 11.5.7 Incentre of a triangle

Let $Z_1, Z_2, Z_3$ be non-collinear points. By 5.5.1 the mid-line of $[Z_2Z_1Z_3]$ will meet $[Z_2Z_3]$ in a point $Z_{12}$ where $Z_{12} = (1 - r)Z_2 + rZ_3$, and
\[
\frac{r}{1 - r} = \frac{c}{b}.
\]
By similar arguments the mid-line of $[Z_3Z_2Z_1]$ will meet $[Z_3,Z_1]$ in a point $Z_{13}$ where $Z_{13} = (1 - s)Z_3 + sZ_1$, and
\[
\frac{s}{1 - s} = \frac{a}{c},
\]
and the mid-line of $[Z_1Z_3Z_2]$ will meet $[Z_1,Z_2]$ in a point $Z_{14}$ where $Z_{14} = (1 - t)Z_1 + tZ_2$, and
\[
\frac{t}{1 - t} = \frac{b}{a}.
\]
The product of these three ratios is clearly equal to 1 so (11.5.1) is satisfied. By the cross-bar theorem, $[Z_2,Z_{13}$ will meet $[Z_3,Z_{14}$ in a point $Z_{15}$ and so $Z_2Z_{13}, Z_3Z_{14}$ meet in $Z_{15}$. It follows that $Z_1Z_{12}$ also passes through the point $Z_{15}$.

*Thus the mid-lines of the angle-supports $[Z_2Z_1Z_3,$ $[Z_3Z_2Z_1,$ $[Z_1Z_3Z_2$ for a triangle $[Z_1,Z_2,Z_3]$ are concurrent.* The perpendicular distances from this point $Z_{15}$ to the side-lines of the triangle are equal by Ex.4.4, so the circle with $Z_{15}$ as centre and length of radius these common perpendicular distances will pass through the feet of these perpendiculars.

![Figure 11.11. Incentre of triangle.](image-url)
This circle is called the incircle for the triangle; its centre $Z_{15}$ is called the incentre of the triangle. The three side-lines are tangents to the circle with the points of contact being the feet of the perpendiculars. For the incentre, by (11.5.2) we have the formula

$$Z_{15} = \frac{a}{a+b+c}Z_1 + \frac{b}{a+b+c}Z_2 + \frac{c}{a+b+c}Z_3.$$  \hfill (11.5.5)

11.6 MOBILE COORDINATES

NOTE. In standard vector notation, the vector product or cross product takes us out of the plane $\Pi$ and into solid geometry. Sensed-area gives us half of the magnitude of the vector product and we use that instead. Without the vector product, however, we have not got orientation of the plane $\Pi$ by vector means. We go on to supply this lack.

However the standard vector operations can be awkward in dealing with perpendicularity and distance, and can involve quite a bit of trigonometry, so we also set out a method of reducing unwieldy calculations.

11.6.1 Grassmann’s supplement of a vector

Given any $Z \neq O$, we show that there is a unique $W$ such that

$$|O, W| = |O, Z|, \ OW \perp OZ, \ \delta_F(O, Z, W) > 0.$$  

Proof. With $Z \equiv (x, y)$, $W \equiv (u, v)$ these require

$$x^2 + y^2 = u^2 + v^2, \ ux + vy = 0, \ xv - yu > 0.$$  

By the middle one of these

$$\begin{vmatrix} x & y \\ -v & u \end{vmatrix} = 0,$$

so the rows of this are linearly dependent. Thus we have $r(x, y) + s(-v, u) = (0, 0)$, for some $(r, s) \neq (0, 0)$. We cannot have $r = 0$ as that would imply $W = O$ and so $Z = O$. Then

$$x = \frac{s}{r}, \ y = -\frac{s}{r}u,$$

so by the first property above

$$x^2 + y^2 = \frac{s^2}{r^2} (x^2 + y^2).$$

Thus we have either $s/r = 1$, so that $u = -y, \ v = x$, for which $2\delta_F(O, Z, W) = x^2 + y^2 > 0$, or we have $s/r = -1$, so that $u = y, \ v = -x$, for which $2\delta_F(O, Z, W) = -(x^2 + y^2) < 0$. Thus the unique solution is $u = -y, \ v = x.$
For any \( Z \in \Pi, Z \neq O \), we define \( \overrightarrow{OZ} = \overrightarrow{OW} \) where \( Z \equiv (x,y) \), \( W \equiv (-y,x) \), and call this the **Grassmann supplement** of \( \overrightarrow{OZ} \). This clearly has the properties

\[
(\overrightarrow{OZ_1} + \overrightarrow{OZ_2})^\perp = \overrightarrow{OZ_1}^\perp + \overrightarrow{OZ_2}^\perp,
\]

\[
(k\overrightarrow{OZ})^\perp = k(\overrightarrow{OZ})^\perp,
\]

\[
(\overrightarrow{OZ})^\perp = -\overrightarrow{OZ}.
\]

### 11.6.2

In \( F \) we take \(|O,I| = |O,J| = 1\). If \(|O,Z| = 1\) and \( \theta \) is the angle in \( \mathcal{A}_F \) with support \( |IOZ| \), then we recall from 9.2.2 that \( Z \equiv (x,y) \) where \( x = \cos \theta \), \( y = \sin \theta \). As \( I \equiv (1,0) \), \( J \equiv (0,1) \), we note that

\[
\overrightarrow{OI}^\perp = \overrightarrow{OJ}, \quad \overrightarrow{OZ} = \cos \theta \overrightarrow{OI} + \sin \theta \overrightarrow{OJ}, \quad \overrightarrow{OZ}^\perp = -\sin \theta \overrightarrow{OI} + \cos \theta \overrightarrow{OJ}.
\]

Suppose that we also have \( \overrightarrow{OW} = \cos \phi \overrightarrow{OI} + \sin \phi \overrightarrow{OJ} \). Then by 11.4.1 we have

\[
\overrightarrow{OW} = r\overrightarrow{OZ} + s\overrightarrow{OZ}^\perp
\]

where

\[
r = \cos \phi \cos \theta + \sin \phi \sin \theta, \quad s = \sin \phi \cos \theta - \cos \phi \sin \theta.
\]

By the addition formulae we recognise that

\[
r = \cos \angle \mathcal{A}_F ZOW, \quad s = \sin \angle \mathcal{A}_F ZOW.
\]

### 11.6.3 Handling a triangle

Although for a triangle \([Z_1,Z_2,Z_3]\), we have the vector form for the centroid as (11.5.3) and for the incentre as (11.5.5) where as usual \( a = |Z_2,Z_3|, b = |Z_3,Z_1|, c = |Z_1,Z_2| \), neither this formula for the incentre, nor the more awkward formula for the orthocentre, are convenient for applications and generalization. In 7.2.3 we noted that a unique circle passes through the vertices of a triangle \([Z_1,Z_2,Z_3]\). It is called the **circumcircle** of this triangle and its centre is called the **circumcentre**. It is possible to find an expression for the circumcentre in terms of the vertices as in 11.4.4 but it is tedious to cover all the cases. For these reasons we consider the following way of representing any triangle.
Given non-collinear points \( Z_1, Z_2, Z_3 \), by 11.4.1 we can express

\[
\overrightarrow{OZ_1} = \overrightarrow{OZ_2} + p_1(\overrightarrow{OZ_3} - \overrightarrow{OZ_2}) + q_1(\overrightarrow{OZ_3} - \overrightarrow{OZ_2})^\perp,
\]

for unique real numbers \( p_1 \) and \( q_1 \), not both equal to 0. This is the geometrical background but the manipulations are simpler if we use complex coordinates instead.

In (11.6.1) for any \( Z \neq O \) we take \( Z \sim z \) where \( z = x + iy \) and \( W \sim w \) where \( w = u + iv \). Then we note that \( iz = -y + ix \) and so \( W = Z^\perp \) if and only if \( w = iz \). Then for \( Z_1 \sim z_1, Z_2 \sim z_2, Z_3 \sim z_3 \) we write

\[
z_1 - z_2 = p_1(z_3 - z_2) + q_1i(z_3 - z_2) = (p_1 + q_1i)(z_3 - z_2),
\]

that is

\[
(x_1 - x_2, y_1 - y_2) = (p_1(x_3 - x_2) - q_1(y_3 - y_2), p_1(y_3 - y_2) + q_1(x_3 - x_2)).
\]

We coin the name mobile coordinates of the point \( Z_1 \) with respect to \( (Z_2, Z_3) \) and \( \mathcal{F} \), for the pair \( (p_1, q_1) \).

It follows immediately that \(|Z_1, Z_2| = \sqrt{p_1^2 + q_1^2}|Z_2, Z_3| \), and as from (11.6.1) \( z_1 - z_3 = (p_1 - 1 + q_1i)(z_3 - z_2) \) we also have \(|Z_3, Z_1| = \sqrt{(p_1 - 1)^2 + q_1^2}|Z_2, Z_3| \). From

\[
\begin{align*}
\frac{z_3 - z_1}{z_2 - z_1} &= \frac{p_1 - 1 + q_1i}{p_1 + q_1i}, & z_1 - z_2 &= p_1 - q_1i, & z_2 - z_3 &= \frac{1}{1 - p_1 + q_1i},
\end{align*}
\]

with \( \alpha = \angle_{\mathcal{F}}Z_2Z_3Z_1, \beta = \angle_{\mathcal{F}}Z_3Z_2Z_1, \gamma = \angle_{\mathcal{F}}Z_1Z_3Z_2 \), we have that

\[
\begin{align*}
\text{cis } \alpha &= \frac{(p_1 - 1 + q_1i)(p_1 - q_1i)}{\sqrt{p_1^2 + q_1^2}} = \frac{p_1 + q_1i}{\sqrt{p_1^2 + q_1^2}}, & \text{cis } \beta &= \frac{1}{\sqrt{p_1^2 + q_1^2}}, & \text{cis } \gamma &= \frac{1 - p_1 + q_1i}{\sqrt{(1 - p_1)^2 + q_1^2}}.
\end{align*}
\]

We also have that

\[
\begin{align*}
p_1 + iq_1 &= \frac{p_1^2 + q_1^2}{\sqrt{p_1^2 + q_1^2}} \text{cis } \beta = \frac{c}{a} \text{cis } \beta, & 1 - p_1 - iq_1 &= \frac{(p_1 - 1)^2 + q_1^2}{\sqrt{(p_1 - 1)^2 + q_1^2}} \text{cis } \gamma = \frac{b}{a} \text{cis } \gamma, & p_1(p_1 - 1) + q_1^2 + iq_1 &= \frac{bc}{a^2} \text{cis } \alpha.
\end{align*}
\]

Thus we have in terms of \( p_1 \) and \( q_1 \), the ratios of the lengths of the sides and cosines and sines of the angles. Moreover, it is easily calculated that

\[
\delta_{\mathcal{F}}(Z_1, Z_2, Z_3) = \frac{q_1}{2}|Z_2, Z_3|^2,
\]

so the orientation of this triple is determined by the sign of \( q_1 \).
Note too that if 
\[ z - z_2 = (p + qi)(z_3 - z_2), \quad z' - z_2 = (p' + q'i)(z_3 - z_2), \]
then 
\[ |z' - z| = |p' - p + (q' - q)i| |z_3 - z_2|, \]
and so 
\[
|Z, Z'| = \sqrt{(p' - p)^2 + (q' - q)^2} |Z_2, Z_3| = a \sqrt{(p' - p)^2 + (q' - q)^2}. \tag{11.6.3}
\]

### 11.6.4 Circumcentre of a triangle

To make our notation consistent we now use the notation 
\([Z_1, Z_2, Z_3]\) for the triangle \([A, B, C]\) in 7.2.3 and \(Z_{16}\) for its circumcentre \(D\). As usual we denote by \(Z_4, Z_5, Z_6\) the mid-points of the sides 
\([Z_2, Z_3], [Z_3, Z_1], [Z_1, Z_2]\), respectively. We note that points \(Z\) on the perpendicular bisector of 
\([Z_2, Z_3]\) have complex coordinates of the form 
\[ z = z_2 + (\frac{1}{2} + qi)(z_3 - z_2), \]
where \(q \in \mathbb{R}\).

We also have \(z_6 = \frac{1}{2}(z_1 + z_2)\). As we are to have \(ZZ_6 \perp Z_1Z_2\) we must have 
\[ z_2 + (\frac{1}{2} + qi)(z_3 - z_2) - \frac{1}{2}(z_1 + z_2) = ur(z_1 - z_2), \]
for some real number \(r\). Then 
\[
z_2 + (\frac{1}{2} + qi)(z_3 - z_2) - \frac{1}{2}[2z_2 + (p_1 + q_1i)(z_3 - z_2)] = ur(z_1 - z_2), \\
[\frac{1}{2} + qi - \frac{1}{2}(p_1 + q_1i) - ur(p_1 + q_1i)](z_3 - z_2) = 0, \\
\frac{1}{2}p_1 - rq_1 - \frac{1}{2} + (\frac{1}{2}q_1 + rp_1)i = q\]
Thus we must have 
\[ q = \frac{1}{2}q_1 + rp_1, \quad rq_1 = \frac{1}{2}p_1 - \frac{1}{2}, \]
from which we obtain the solutions \(r = \frac{p_1}{2q_1}\) and then \(q = \frac{1}{2q_1} [p_1^2 + q_1^2 - p_1]\).

Thus the circumcentre has complex coordinate 
\[ z_{16} = z_2 + \frac{1}{2} \left[ 1 + \frac{p_1^2 + q_1^2 - p_1}{q_1} \right] (z_3 - z_2). \tag{11.6.4} \]
By Pythagoras’ theorem
\[|z_{16} - z_2|^2 = |z_4 - z_2|^2 + |z_4 - z_{16}|^2\]
\[= \left\{ \frac{1}{2} |z_3 - z_2|^2 \right\}^2 + \left\{ |q|^2 |z_3 - z_2| \right\}^2\]
\[= \left\{ \frac{1}{4} \left( \frac{q_1^2 + p_1^2 - p_1}{2q_1} \right)^2 \right\} |z_3 - z_2|^2\]
\[= \frac{a^2}{4q_1^2} \left\{ (q_1^2 + p_1^2 - p_1)^2 + q_1^2 \right\}.
\]
Thus the radius length of the circumcircle is
\[|z_{16} - z_2| = \frac{a}{2|q_1|} \sqrt{q_1^2 + |p_1^2 + q_1^2 - p_1|^2}. \tag{11.6.5}\]

In fact we can also derive the formula (11.6.5) slightly differently as follows. Directly from (11.6.4) we have that
\[|z_{16} - z_2|^2 = \frac{1}{4} \left| 1 + \left( \frac{p_1^2 + q_1^2}{q_1} - \frac{p_1}{q_1} \right) \right|^2 a^2 \]
\[= \frac{1}{4} \left[ 1 + \left( \frac{p_1^2 + q_1^2}{q_1} - \frac{p_1}{q_1} \right)^2 \right] a^2 \]
\[= \frac{a^2}{4q_1^2} \left( q_1^2 + |p_1^2 + q_1^2 - p_1|^2 \right).
\]

We can deduce from this material a formula for the circumcentre in terms of areal coordinates. For by (11.6.2)
\[p_1^2 - p_1 + q_1^2 = \frac{bc}{a^2} \cos \alpha, \quad q_1 = \frac{bc}{a^2} \sin \alpha,\]
so that \(z = z_2 + \frac{1}{2} (1 + \cot \alpha i)(z_3 - z_2)\). Then by (11.6.1) we have
\[x - x_2 = \frac{1}{2} (x_3 - x_2) - \frac{1}{2} \cot \alpha (y_3 - y_2), \quad y - y_2 = \frac{1}{2} \cot \alpha (x_3 - x_2) + \frac{1}{2} (y_3 - y_2).
\]
From this we have that
\[\delta_{\mathcal{F}}(Z, Z_2, Z_3) = \delta_{\mathcal{F}}(Z - Z_2, O, Z_3 - Z_2)\]
\[= \frac{1}{4} \cot \alpha \left[ (x_3 - x_2)^2 + (y_3 - y_2)^2 \right] = \frac{1}{4} a^2 \cot \alpha.
\]
As \(\delta_{\mathcal{F}}(Z_1, Z_2, Z_3) = \frac{1}{2} q_1 a^2 = \frac{1}{2} bc \sin \alpha\) we have
\[\frac{\delta_{\mathcal{F}}(Z, Z_2, Z_3)}{\delta_{\mathcal{F}}(Z_1, Z_2, Z_3)} = \frac{1}{2} \frac{a^2 \cot \alpha}{bc \sin \alpha},\]
and by use of the sine rule this is seen to be equal to
\[\frac{1}{2} \frac{\cos \alpha}{\sin \beta \sin \gamma}.
\]
By cyclic rotation we can write down the other two coefficients and so have

\[
Z_{16} = \frac{1}{2} \cos \alpha \sin \beta \sin \gamma Z_1 + \frac{1}{2} \cos \beta \sin \gamma \sin \alpha Z_2 + \frac{1}{2} \cos \gamma \sin \alpha \sin \beta Z_3.
\]

That the sum of the coefficients here is equal to 1 follows from the identity

\[
\sin 2\alpha + \sin 2\beta + \sin 2\gamma = 4 \sin \alpha \sin \beta \sin \gamma,
\]

for the angles of a triangle. For

\[
\sin 2\alpha \sin \beta \sin \gamma = \sin (\alpha + \beta) \cos (\alpha - \beta) + 2 \sin \gamma \cos \gamma.
\]

11.6.5 Other distinguished points for a triangle

For the centroid \( Z_7 \) of \([Z_1, Z_2, Z_3]\) we have by 11.5.3 that \( z_7 = \frac{1}{3} (z_1 + z_2 + z_3) \) and so

\[
z_7 - z_2 = \frac{1}{3} (z_1 + z_2 + z_3) - z_2 = \frac{1}{3} (z_1 - z_2) + \frac{1}{3} (z_3 - z_2)
\]

\[
= \frac{1}{3} (p_1 + q_1)(z_3 - z_2) + \frac{1}{3} (z_3 - z_2)
\]

\[
= \frac{1}{3} (p_1 + 1 + q_1)(z_3 - z_2).
\]

This gives the complex coordinate of the centroid.

We next turn to the orthocentre of this triangle. Points \( Z \) on the line through \( Z_1 \) perpendicular to \( Z_2Z_3 \) have complex coordinates of the form

\[
z = z_2 + (p_1 + q_1)(z_3 - z_2) = z_3 + (p_1 - 1 + q_1)(z_3 - z_2)
\]

\[
= z_3 + \frac{p_1 - 1 + q_1}{p_1 + q_1}(z_1 - z_2).
\]

For \( Z_3Z \) to be also perpendicular to \( Z_1Z_2 \) we also need the coefficient of \( z_1 - z_2 \) here to be purely imaginary. Thus we need

\[
(p_1 - 1)p_1 + qq_1 = 0 \quad \text{i.e.} \quad q = -\frac{(p_1 - 1)p_1}{q_1},
\]

and so obtain

\[
z_{11} = z_2 + p_1 \left( 1 - \frac{p_1 - 1}{q_1} \right)(z_3 - z_2),
\]

as the complex coordinate of the orthocentre.

It takes more of an effort to deal with the incentre. The point with complex coordinate \( z_2 + \frac{1}{|Z_2Z_3|}(z_3 - z_2) \) lies on the half-line \( [Z_2, Z_3] \) at a unit distance from \( Z_2 \).
Similarly the point with complex coordinate \( z_2 + \frac{1}{|Z_2, Z_3|} (z_3 - z_2) \), lies on the half-line \([Z_2, Z_1]\) at a unit distance from \(Z_2\). We wish to consider the mid-point of these points with complex coordinates

\[
z_2 + \frac{1}{|Z_2, Z_3|} (z_3 - z_2), \quad z_2 + \frac{1}{|Z_2, Z_1|} (z_1 - z_2).
\]

Now \( z_1 - z_2 = (p_1 + iq_1)(z_3 - z_2) \) so that

\[
|z_1 - z_2| = |p_1 + iq_1||z_3 - z_2| = \sqrt{p_1^2 + q_1^2}|z_3 - z_2|.
\]

Then

\[
\frac{z_1 - z_2}{|Z_2, Z_1|} = \frac{p_1 + iq_1}{\sqrt{p_1^2 + q_1^2}} \frac{z_3 - z_2}{|Z_2, Z_3|}.
\]

The mid-point of these two points has complex coordinate

\[
z_2 + \frac{1}{2|Z_2, Z_3|} \left[ z_3 - z_2 + \frac{1}{\sqrt{p_1^2 + q_1^2}} (z_1 - z_2) \right]
\]

\[
= z_2 + \frac{1}{2|Z_2, Z_3|} \left[ z_3 - z_2 + \frac{p_1 + iq_1}{\sqrt{p_1^2 + q_1^2}} (z_3 - z_2) \right]
\]

\[
= z_2 + \frac{1}{2|Z_2, Z_3|} \left[ 1 + \frac{p_1 + iq_1}{\sqrt{p_1^2 + q_1^2}} \right] (z_3 - z_2).
\]

Then points on the midline of \([Z_1, Z_2, Z_3]\) then have complex coordinates of the form

\[
z_2 + \frac{r}{2|Z_2, Z_3|} \left[ 1 + \frac{p_1 + iq_1}{\sqrt{p_1^2 + q_1^2}} \right] (z_3 - z_2),
\]

for real numbers \(r\).

By a similar argument the point with complex coordinate \( z_3 + \frac{1}{|Z_3, Z_3|} (z_2 - z_3) \) lies on the half-line \([Z_3, Z_2]\) at a unit distance from \(Z_3\). Also the point with complex coordinate \( z_3 + \frac{1}{|Z_3, Z_1|} (z_1 - z_3) \), lies on the half-line \([Z_3, Z_1]\) at a unit distance from \(Z_3\). We wish to consider the mid-point of these points with complex coordinates

\[
z_3 + \frac{1}{|Z_2, Z_3|} (z_2 - z_3), \quad z_3 + \frac{1}{|Z_3, Z_1|} (z_1 - z_3).
\]

As preparation we note that

\[
z_1 = z_2 + (p_1 + iq_1)(z_3 - z_2) = z_3 + (p_1 - 1 + iq_1)(z_3 - z_2)
\]

\[
z_1 - z_3 = (1 - p_1 - iq_1)(z_3 - z_2), \quad |Z_1, Z_3| = \sqrt{(1 - p_1)^2 + q_1^2}|Z_2, Z_3|,
\]

\[
\frac{z_1 - z_3}{|Z_3, Z_1|} = \left[ \frac{1 - p_1 - iq_1}{\sqrt{(1 - p_1)^2 + q_1^2}} \right] \frac{z_2 - z_3}{|Z_2, Z_3|}.
\]
The mid-point sought is

\[
z_3 + \frac{1}{2|Z_2, Z_3|} \left[ z_2 - z_3 + \frac{1 - p_1 - iq_1}{\sqrt{(1 - p_1)^2 + q_1^2}} (z_2 - z_3) \right]
\]

\[
= z_3 + \frac{1}{2|Z_2, Z_3|} \left[ 1 + \frac{1 - p_1 - iq_1}{\sqrt{(1 - p_1)^2 + q_1^2}} \right]
\]

Then points on the midline of \(|Z_2Z_3Z_1|\) have complex coordinates of the form

\[
z_3 + \frac{s}{2|Z_2, Z_3|} \left( \frac{1 - p_1 + q_1 t}{\sqrt{(p_1 - 1)^2 + q_1^2}} \right) (z_2 - z_3)
\]

for real numbers \(s\).

For a point of intersection of the two mid-lines we need

\[
z_2 + \frac{r}{2|Z_2, Z_3|} \left( 1 + \frac{p_1 + q_1 t}{\sqrt{p_1^2 + q_1^2}} \right) (z_3 - z_2)
\]

\[
= z_3 + \frac{s}{2|Z_2, Z_3|} \left( 1 + \frac{1 - p_1 - q_1 t}{\sqrt{(p_1 - 1)^2 + q_1^2}} \right) (z_2 - z_3)
\]

\[
= z_3 - \frac{s}{2|Z_2, Z_3|} \left( 1 + \frac{1 - p_1 - q_1 t}{\sqrt{(p_1 - 1)^2 + q_1^2}} \right) (z_3 - z_2).
\]

Then

\[
z_3 - z_2 +
\]

\[
\left[ \frac{-r}{2|Z_2, Z_3|} \left( 1 + \frac{p_1 + iq_1}{\sqrt{p_1^2 + q_1^2}} \right) - \frac{s}{2|Z_2, Z_3|} \left( 1 + \frac{1 - p_1 - iq_1}{\sqrt{(1 - p_1)^2 + q_1^2}} \right) \right] (z_3 - z_2) = 0,
\]

\[
1 + \frac{-r}{2|Z_2, Z_3|} \left( 1 + \frac{p_1 + iq_1}{\sqrt{p_1^2 + q_1^2}} \right) - \frac{s}{2|Z_2, Z_3|} \left( 1 + \frac{1 - p_1 - iq_1}{\sqrt{(1 - p_1)^2 + q_1^2}} \right) = 0.
\]

Equating to 0 the imaginary part we obtain

\[
- \frac{rq}{\sqrt{p_1^2 + q_1^2}} + \frac{sq}{\sqrt{(1 - p_1)^2 + q_1^2}} = 0,
\]

and the real part

\[
1 - \frac{r}{2|Z_2, Z_3|} \left( 1 + \frac{p_1}{\sqrt{p_1^2 + q_1^2}} \right) - \frac{s}{2|Z_2, Z_3|} \left( 1 + \frac{1 - p_1}{\sqrt{(1 - p_1)^2 + q_1^2}} \right) = 0.
\]
Assuming \( q_1 \neq 0 \) we have the pair of equations

\[
\frac{1}{\sqrt{p_1^2 + q_1^2}} r - \frac{1}{\sqrt{(1-p_1)^2 + q_1^2}} s = 0,
\]

\[
\left(1 + \frac{p_1}{\sqrt{p_1^2 + q_1^2}}\right) r + \left(1 + \frac{1-p_1}{\sqrt{(1-p_1)^2 + q_1^2}}\right) s = 2|Z_2, Z_3|.
\]  \hspace{1cm} (11.6.8)

We denote by \( D_1 \) the value of the determinant of coefficients on the left-hand side:

\[
\begin{vmatrix}
\frac{1}{\sqrt{p_1^2 + q_1^2}} & -\frac{1}{\sqrt{(1-p_1)^2 + q_1^2}} \\
1 + \frac{p_1}{\sqrt{p_1^2 + q_1^2}} & 1 + \frac{1-p_1}{\sqrt{(1-p_1)^2 + q_1^2}}
\end{vmatrix}
\]

and have

\[
D_1 = \frac{\sqrt{(1-p_1)^2 + q_1^2} + \sqrt{p_1^2 + q_1^2} + 1}{\sqrt{p_1^2 + q_1^2} \sqrt{(1-p_1)^2 + q_1^2}}.
\]

We denote by \( D_2 \) the value of the determinant

\[
\begin{vmatrix}
0 & -\frac{1}{\sqrt{(1-p_1)^2 + q_1^2}} \\
2|Z_2, Z_3| & 1 + \frac{1-p_1}{\sqrt{(1-p_1)^2 + q_1^2}}
\end{vmatrix}
\]

which has the value

\[
D_2 = \frac{2|Z_2, Z_3|}{\sqrt{(1-p_1)^2 + q_1^2}}.
\]

Then we have the solution

\[
r = \frac{D_2}{D_1} = \frac{2|Z_2, Z_3| \sqrt{p_1^2 + q_1^2}}{\sqrt{(1-p_1)^2 + q_1^2} \sqrt{p_1^2 + q_1^2} + 1}.
\]

Thus the point of intersection from this bisector is

\[
z_2 + \frac{\sqrt{p_1^2 + q_1^2}}{\sqrt{(1-p_1)^2 + q_1^2} + \sqrt{p_1^2 + q_1^2} + 1} \left[1 + \frac{p_1 + iq_1}{\sqrt{p_1^2 + q_1^2}}\right] (z_3 - z_2),
\]  \hspace{1cm} (11.6.9)

which is thus the incentre \( Z_{15} \).
11.6.6 Euler line of a triangle

With the notation $Z_7, Z_{16}, Z_{11}$ for the centroid, circumcentre and orthocentre, respectively, of a triangle $[Z_1, Z_2, Z_3]$ we have the formulae

\[
\begin{align*}
Z_7 - Z_2 &= \frac{1}{3}(p_1 + 1 + q_1 i)(z_3 - z_2), \\
Z_{16} - Z_2 &= \frac{1}{2} \left(1 + \frac{p_1^2 - p_1 + q_1^2}{q_1} \right) (z_3 - z_2), \\
Z_{11} - Z_2 &= p_1 \left(1 - \frac{p_1 - 1}{q_1} \right) (z_3 - z_2).
\end{align*}
\]

It is straightforward to check that

\[
\frac{2}{3}z_{16} + \frac{1}{3}z_{11} = z_2 + \frac{2}{3}(z_{16} - z_2) + \frac{1}{3}(z_{11} - z_2) = z_7,
\]

and so $Z_7 \in Z_{16}Z_{11}$.

Thus we have shown that the centroid, circumcentre and orthocentre of any triangle are collinear. This is a result due to Euler, after whom this line of collinearity is named the Euler line of the triangle.

11.6.7 Similar triangles

For any two triangles $[Z_1, Z_2, Z_3]$ and $[Z'_1, Z'_2, Z'_3]$ suppose that we have $z_1 = z_2 + (p_1 + q_1 i)(z_3 - z_2)$, $z'_1 = z'_2 + (p'_1 + q'_1 i)(z'_3 - z'_2)$, where $(p_1, q_1), (p'_1, q'_1)$ are couples of real numbers, neither being $(0, 0)$. Then these triangles are similar in the correspondence $(Z_1, Z_2, Z_3) \rightarrow (Z'_1, Z'_2, Z'_3)$ if and only if $p'_1 = p_1$, $q'_1 = \pm q_1$.

**Proof.** First suppose that $p'_1 = p_1$, $q'_1 = q_1$ so that $z_1 = z_2 + (p_1 + q_1 i)(z_3 - z_2)$, $z'_1 = z'_2 + (p'_1 + q'_1 i)(z'_3 - z'_2)$. Then we have that

\[
\angle Z_3Z_2Z_1^\circ = \angle Z'_3Z'_2Z_1^\circ, \quad \angle Z_1Z_3Z_2^\circ = \angle Z'_1Z'_3Z_2^\circ.
\]

It follows by 5.3.2 that the measures of the corresponding angles of these triangles are equal, and so the triangles are similar, with the lengths of corresponding sides proportional. Moreover, the triples $(Z_1, Z_2, Z_3)$ and $(Z'_1, Z'_2, Z'_3)$ are similarly oriented.
Next suppose that \( z_1 = z_2 + (p_1 + qi)(z_3 - z_2), \) \( z'_1 = z'_2 + (p_1 - qi)(z'_3 - z'_2) \). By an analogous argument the triangles are still similar, and now the triples \((Z_1, Z_2, Z_3)\) and \((Z'_1, Z'_2, Z'_3)\) are oppositely oriented.

Conversely, suppose that \([Z_1, Z_2, Z_3]\) and \([Z'_1, Z'_2, Z'_3]\) are similar triangles in the correspondence \((Z_1, Z_2, Z_3) \to (Z'_1, Z'_2, Z'_3)\). Let \( W_1 \) be the foot of the perpendicular from \( Z_1 \) to \( Z_2 Z_3 \), and from parametric equations of \( Z_2 Z_3 \) choose \( p_1 \in \mathbb{R} \) so that \( w_1 = z_2 + p_1(z_3 - z_2) \). Then
\[
\frac{|Z_2, W_1|}{|Z_2, Z_3|} = |p_1|,
\]
and \( p_1 \) is positive or negative according or not as \( W_1 \) is on the same or opposite side of \( Z_2 \) as \( Z_3 \) is on the line \( Z_2 Z_3 \), that is according as the wedge-angle \( \angle Z_2 Z_2 Z_1 \) is acute or obtuse. As \( W_1 Z_1 \perp Z_2 Z_3 \) we can find \( q_1 \in \mathbb{R} \) so that \( z_1 - w_1 = q_1(z_3 - z_2) \). Then
\[
\frac{|Z_1, W_1|}{|Z_2, Z_3|} = |q_1|,
\]
and \( q_1 \) is positive or negative according as \((Z_1, Z_2, Z_3)\) is positively or negatively oriented.

As the lengths of the sides of the two triangles are proportional, we have
\[
|Z'_2, Z'_3| = k|Z_2, Z_3|, \quad |Z_3, Z_1| = k|Z'_3, Z'_1|, \quad |Z'_1, Z'_2| = k|Z_1, Z_2|,
\]
for some \( k > 0 \). Let \( W'_1 \) be the foot of the perpendicular from \( Z_4 \) to the line \( Z_5 Z_6 \). Then the triangles \([Z_1, Z_2, W_1]\) and \([Z'_1, Z'_2, W'_1]\) are similar, so we have that
\[
\frac{|Z'_2, W'_1|}{|Z_2, W_1|} = \frac{|Z'_1, Z'_2|}{|Z_1, Z_2|} = k.
\]
It follows that
\[
|Z'_2, W'_1| = k|Z_2, W_1| = k|p_1||Z_2, Z_3| = |p_1||Z'_2, Z'_3|.
\]
But \( W'_1 \) is on the same side of the point \( Z'_2 \) on the line \( Z'_2 Z'_3 \) as \( Z'_3 \) is if the wedge-angle \( \angle Z'_3 Z'_2 Z'_1 \) is acute, and on the opposite side if this angle is obtuse. Hence we have that
\[
w'_1 - z'_2 = p_1(z'_3 - z_2).
\]
As \( Z'_1 W'_1 \perp Z'_2 Z'_3 \), we have \( z'_1 - w'_1 = jt(z'_3 - z'_2) \) for some \( j \in \mathbb{R} \), and then \( |Z'_1, W'_1| = |j||Z'_1, Z'_3| \). But
\[
\frac{|Z'_1, W'_1|}{|Z_1, W_1|} = \frac{|Z'_1, Z'_3|}{|Z_1, Z_2|} = \frac{|Z'_1, Z'_3|}{|Z_2, Z_3|},
\]
so
\[
\frac{|Z'_1, W'_1|}{|Z'_2, Z'_3|} = \frac{|Z_1, W_1|}{|Z_2, Z_3|} = |q_1|.
\]
Hence \( j = \pm q_1 \) and we are to take the plus if \((Z_1, Z_2, Z_3)\) and \((Z'_1, Z'_2, Z'_3)\) have the same orientation, the minus if the opposite orientation.

Thus our mobile coordinates \((p_1, q_1)\) are intimately connected with similarity of triangles.
11.6.8 Centroids of similar triangles erected on the sides of a triangle

Given an arbitrary triangle $[Z_1, Z_2, Z_3]$, if we consider points $Z_4$, $Z_5$ and $Z_6$ defined by

$$z_4 = z_2 + (p_1 + q_1 t)(z_3 - z_2), \quad z_5 = z_3 + (p_1 + q_1 t)(z_1 - z_3),$$
$$z_6 = z_1 + (p_1 + q_1 t)(z_2 - z_1),$$

for some non-zero real numbers $p_1$ and $q_1$, then we have triangles $[Z_2, Z_3, Z_4]$, $[Z_3, Z_1, Z_5]$, $[Z_1, Z_2, Z_6]$ erected on the sides $[Z_2, Z_3]$, $[Z_3, Z_1]$ and $[Z_1, Z_2]$, respectively, which are similar to each other and have the same orientation as each other.

We denote the centroid of $[Z_1, Z_2, Z_3]$ by $Z_7$ so that $z_7 = \frac{1}{3}(z_1 + z_2 + z_3)$ and the centroid of $[Z_4, Z_5, Z_6]$ by $Z_7'$ so that

$$z_7' = \frac{1}{3}[z_2 + (p_1 + q_1 t)(z_3 - z_2) + z_3 + (p_1 + q_1 t)(z_1 - z_3) + z_1 + (p_1 + q_1 t)(z_2 - z_1)],$$
$$= \frac{1}{3}[z_2 + z_3 + z_1] + \frac{1}{3}(p_1 + q_1 t)[(z_3 - z_2) + (z_1 - z_3) + (z_2 - z_1)]$$
$$= \frac{1}{3}(z_1 + z_2 + z_3).$$

Hence $Z_7'$ is the same point as $Z_7$.

First we denote the centroid of $[Z_2, Z_3, Z_4]$ by $Z_7^{(i)}$ and then

$$z_7^{(i)} = \frac{1}{3}[z_2 + z_3 + z_4] = \frac{1}{3}[z_2 + z_3 + z_2 + (p_1 + q_1 t)(z_3 - z_2)].$$

Secondly we denote the centroid of $Z_3, Z_1, Z_5$ by $Z_7^{(ii)}$ and then

$$z_7^{(ii)} = \frac{1}{3}[z_3 + z_1 + z_3 + (p_1 + q_1 t)(z_1 - z_3)].$$

Finally we denote the centroid of $[Z_1, Z_2, Z_6]$ by $Z_7^{(iii)}$ and then

$$z_7^{(iii)} = \frac{1}{3}[z_1 + z_2 + z_1 + (p_1 + q_1 t)(z_2 - z_1)].$$

Then we have that

$$z_7^{(i)} + z_7^{(ii)} + z_7^{(iii)}$$
$$= \frac{1}{3}[(2z_2 + z_3 + 2z_3 + z_1 + 2z_1 + z_2) + (p_1 + q_1 t)(z_3 - z_2 + z_1 - z_3 + z_2 - z_1)]$$
$$= z_1 + z_2 + z_3.$$

It follows that the centroid of the triangle $[Z_7^{(i)}, Z_7^{(ii)}, Z_7^{(iii)}]$ is the same point as the centroid $Z_7$ of the original triangle $[Z_1, Z_2, Z_3]$. 
11.6.9 Circumcentres of similar triangles on sides of triangle

In a more complicated fashion than in the last subsection, for an arbitrary triangle \([Z_1, Z_2, Z_3]\) suppose that we take points \(Z_4, Z_5\) and \(Z_6\) so that
\[
\begin{align*}
  z_4 &= z_2 + (p_1 + q_1 t)(z_3 - z_2), \\
  z_3 &= z_1 + (p_1 + q_1 t)(z_5 - z_1), \\
  z_2 &= z_6 + (p_1 + q_1 t)(z_1 - z_6),
\end{align*}
\]
so that we have similar triangles once again on the sides of the original triangle but now in the correspondences \((Z_2, Z_3, Z_4) \rightarrow (Z_1, Z_5, Z_3) \rightarrow (Z_6, Z_1, Z_2)\). We let \(Z_{16}^{(i)}, Z_{16}^{(ii)}, Z_{16}^{(iii)}\) be the circumcentres of these three similar triangles, so that by (1.6.4) we have
\[
\begin{align*}
  z_{16}^{(i)} - z_2 &= \frac{1}{2} \left( 1 + \frac{p_1^2 - p_1 + q_1^2}{q_1} t \right) (z_3 - z_2), \\
  z_{16}^{(ii)} - z_1 &= \frac{1}{2} \left( 1 + \frac{p_1^2 - p_1 + q_1^2}{q_1} t \right) (z_5 - z_1), \\
  z_{16}^{(iii)} - z_6 &= \frac{1}{2} \left( 1 + \frac{p_1^2 - p_1 + q_1^2}{q_1} t \right) (z_1 - z_6).
\end{align*}
\]
But by (11.6.9) we have \(z_5 - z_1 = \frac{1}{p_1 + q_1 t}(z_3 - z_1)\) and \(z_2 - z_1 = (1 - p_1 - q_1 t)(z_6 - z_1)\), so that \(z_6 - z_1 = \frac{1}{1 - p_1 - q_1 t}(z_2 - z_1)\).
Also, by (11.6.12)
\[
(z_{16}^{(iii)} + (p_1 + q_1 t)(z_{16}^{(iii)} - z_{16}^{(iii)})) \\
= (1 - p_1 - q_1 t)z_{16}^{(iii)} + (p_1 + q_1 t)z_{16}^{(iii)} \\
= (1 - p_1 - q_1 t)(z_{16}^{(iii)} - z_1) + (p_1 + q_1 t)(z_{16}^{(iii)} - z_1) + (1 - q_1 t + z_1 t)z_1 \\
= (1 - p_1 - q_1 t)(z_{16}^{(iii)} - z_1) + (p_1 + q_1 t)(z_{16}^{(iii)} - z_1) + z_1 \\
= \frac{1}{2} \left[ 1 - \frac{p_1^2 - p_1 + q_1^2}{q_1} \right] (z_2 - z_1) + \frac{1}{2} \left[ 1 + \frac{p_1^2 - p_1 + q_1^2}{q_1} \right] (z_3 - z_1) + z_1 \\
= \frac{1}{2} (z_2 + z_3) + \frac{1}{2} \left[ \frac{p_1^2 - p_1 + q_1^2}{q_1} \right] (z_3 - z_1 - z_2) \\
= \frac{1}{2} (z_2 + z_3) + \frac{1}{2} \left[ \frac{p_1^2 - p_1 + q_1^2}{q_1} \right] (z_3 - z_1 - (z_2 - z_1)) \\
= \frac{1}{2} (z_2 + z_3) + \frac{1}{2} \left[ \frac{p_1^2 - p_1 + q_1^2}{q_1} \right] (z_3 - z_2) \\
=z_{16}^{(i)}.
\]

It follows that the triangle \([Z_{16}^{(i)}, Z_{16}^{(ii)}, Z_{16}^{(iii)}]\) is also similar to the similar triangles above, in the correspondence \((Z_2, Z_3, Z_4) \rightarrow (Z_{16}^{(iii)}, Z_{16}^{(ii)}, Z_{16}^{(i)}).\)

In the particular case when \(p_1 = 1/2, q_1 = \sqrt{3}/2\), the similar triangles are all equilateral triangles, that is all three sides have equal lengths. In this case the last result is known as \textsc{Napoleon’s theorem}. It is easier to prove than the more general case, as for it we can work just with centroids.

11.6.10 Triangle with vertices the mid-points of sides of given triangle

For a triangle \([Z_1, Z_2, Z_3]\) let \(Z_4, Z_5, Z_6\) be the mid-points of the the sides \([Z_2, Z_3], [Z_3, Z_1], [Z_1, Z_2]\), respectively. Suppose that \(z_1 = z_2 + (p_1 + q_1 t)(z_3 - z_2).\) Now

\[
z_4 = \frac{1}{2}(z_2 + z_3) = z_2 + \frac{1}{2}(z_3 - z_2),
\]

\[
z_5 = \frac{1}{2}(z_3 + z_1) = z_2 + \frac{1}{2}(z_3 - z_2) + \frac{1}{2}[z_2 + (p_1 + q_1 t)(z_3 - z_2)]
\]

\[
= z_2 + \frac{1}{2}(1 + p_1 + q_1 t)(z_3 - z_2),
\]

\[
z_6 = \frac{1}{2}(z_1 + z_2) = \frac{1}{2}[z_2 + (p_1 + q_1 t)(z_3 - z_2)] + z_2 = z_2 + \frac{1}{2}(p_1 + q_1 t)(z_3 - z_2).
\]

Then

\[
z_6 - z_5 = \frac{1}{2}(p_1 + q_1 t - 1 - p_1 - q_1 t)(z_3 - z_2) = -\frac{1}{2}(z_3 - z_2),
\]

\[
z_4 - z_5 = z_2 + \frac{1}{2}(z_3 - z_2) - z_2 - \frac{1}{2}(1 + p_1 + q_1 t)(z_3 - z_2)
\]

\[
= -\frac{1}{2}(p_1 + q_1 t)(z_3 - z_2) = (p_1 + q_1 t)(z_6 - z_5). \tag{11.6.14}
\]

Thus the triangle \([Z_4, Z_5, Z_6]\) is similar to the original triangle \([Z_1, Z_2, Z_3]\).
By (11.6.4) the circumcentre \( Z'_{16} \) of the triangle \([Z_4, Z_5, Z_6]\) is given by

\[
z'_{16} = z_5 + \frac{1}{2} \left[ 1 + \frac{p_1^2 + q_1^2}{q_1} i - \frac{p_1}{q_1} i \right] (z_6 - z_5), \tag{11.6.15}
\]

and if we relate this to the original triangle it becomes

\[
z'_{16} = z_2 + \frac{1}{2} (1 + p_1 + q_1) i (z_3 - z_2) + \frac{1}{2} \left[ 1 + \frac{p_1}{q_1} + \frac{p_1^2 + q_1^2}{2q_1} i \right] (z_3 - z_2) = z_2 + \frac{1}{2} \left[ 1 + p_1 + q_1 i - \frac{p_1}{q_1} - \frac{p_1^2 + q_1^2}{2q_1} i \right] (z_3 - z_2).
\tag{11.6.16}
\]

We now find another point on this circle with centre (11.6.16). The foot \( Z_8 \) of the perpendicular from \( Z_1 \) onto \( Z_2 Z_3 \) has complex coordinate \( z_8 = z_2 + p_1 (z_3 - z_2) \). We seek the circumcentre of the triangle \([Z_4, Z_8, Z_6]\). For the moment let us take

\[
z_4 = z_8 + (p_2 + q_2 i) (z_6 - z_8)
\tag{11.6.17}
\]

from which

\[
z_4 = (1 - p_2 - q_2 i) z_8 + (p_2 + q_2 i) z_6
\]

\[
= (1 - p_2 - q_2 i) [z_2 + p_1 (z_3 - z_2) + (p_2 + q_2 i) z_2 + \frac{1}{2} (p_1 + q_1 i) (z_3 - z_2)]
\]

\[
= (1 - p_2 - q_2 i) [z_2 + p_1 (z_3 - z_2) + (p_2 + q_2 i) \frac{1}{2} (p_1 + q_1 i) (z_3 - z_2)]
\]

\[
= z_2 + \left\{ p_1 (1 - p_2) + \frac{1}{2} (p_2 p_1 - q_2 q_1) + [-p_1 q_2 + \frac{1}{2} (p_2 q_1 + p_1 q_2)] i \right\} (z_3 - z_2)
\]

\[
= z_2 + \frac{1}{2} (z_3 - z_2).
\]

Thus

\[
p_1 (1 - p_2) + \frac{1}{2} (p_2 p_1 - q_2 q_1) + [-p_1 q_2 + \frac{1}{2} (p_2 q_1 + p_1 q_2)] i = \frac{1}{2},
\]

from which

\[
\frac{1}{2} (p_2 q_1 - p_1 q_2) = 0, \quad p_1 (1 - p_2) + \frac{1}{2} (p_2 p_1 - q_2 q_1) = \frac{1}{2}.
\]

As \( p_1 \neq 0 \) we have \( q_2 = \frac{p_2}{p_1} q_1 \). As \( 2 p_1 - 2 p_2 + p_2 p_1 - q_2 q_1 = 1 \) we have \( 2 p_1 - p_1 p_2 = 1 + q_2 q_1 \). Hence \( 2 p_1 - p_1 p_2 = 1 + \frac{p_2}{p_1} q_1^2 \) and so

\[
2 p_1 - 1 = p_2 \left( \frac{q_1^2}{p_1} + p_1 \right), \quad p_2 = \frac{2 p_1 - 1}{q_1^2 + p_1^2},
\]

\[
q_2 = \frac{q_1 (2 p_1 - 1) p_1}{p_1^2 + q_1^2} = \frac{(2 p_1 - 1) q_1}{p_1^2 + q_1^2}.
\]
Then

\[ p_2^2 + q_2^2 = \frac{(2p_1 - 1)^2(p_1^2 + q_1^2)}{(p_1^2 + q_1^2)^2} = \frac{(2p_1 - 1)^2}{p_1^2 + q_1^2}. \]

By (11.6.4) the circumcentre \( Z_{16} \) of the triangle \([Z_1, Z_2, Z_3]\) has complex coordinate

\[ z_{16} = z_2 + \frac{1}{2} \left[ 1 - \frac{p_1}{q_1} + \frac{p_1^2 + q_1^2}{q_1^2} \right] (z_3 - z_2), \]

and so the circumcentre \( z_{16}^{(ii)} \) of the triangle \([Z_4, Z_8, Z_6]\) has complex coordinate

\[
z_{16}^{(ii)} = z_8 + \frac{1}{2} \left[ 1 - \frac{p_2}{q_2} + \frac{p_2^2 + q_2^2}{q_2^2} \right] (z_6 - z_8)
= z_2 + p_1(z_3 - z_2) + \frac{1}{2} \left[ 1 - \frac{p_2}{q_2} + \frac{p_2^2 + q_2^2}{q_2} \right] \left( \frac{1}{2}(p_1 + q_1)(z_3 - z_2) - p_1(z_3 - z_2) \right)
= z_2 + \left[ p_1 + \frac{1}{2}(1 - \frac{p_2}{q_2} + \frac{p_2^2 + q_2^2}{q_2}) \right] (z_3 - z_2)
= z_2 + p_1(z_3 - z_2) + \frac{1}{4} \left[ -p_1 + \frac{p_2}{q_2} - q_1 \frac{p_2^2 + q_2^2}{q_2} + \left[ p_1 \frac{p_2}{q_2} - p_1^2 + q_2^2 \right] (z_3 - z_2) \right]. \quad (11.6.18)

From the values of \( p_2^2 + q_2^2 \) and \( q_2 \), and also of \( p_2/q_2 \) we have

\[ -q_1 \frac{(2p_1 - 1)^2}{p_1^2 + q_1^2} + q_1 \frac{p_1}{q_1} = -(2p_1 - 1) + p_1 = 1 - p_1. \]

Similarly

\[ \frac{p_1}{q_1} \frac{p_2 - p_1^2 + q_2^2}{q_2} = -p_1 \frac{(2p_1 - 1)^2}{p_1^2 + q_1^2} \frac{p_1 + q_1^2}{q_1} \]

\[ = -p_1 \frac{1}{q_1} (2p_1 - 1) + p_1 \frac{q_1}{q_1} = -2p_1 \frac{p_1}{q_1} + p_1 + p_1 \frac{p_1}{q_1}
= (1 - p_1) \frac{p_1}{q_1}. \]

Hence

\[
z_{16}^{(ii)} = z_2 + p_1(z_3 - z_2) + \frac{1}{4} \left[ -p_1 + 1 - p_1 + [((1 - p_1) \frac{p_1}{q_1} + q_1)q_1 \right] \right] (z_3 - z_2)
= z_2 + \frac{1}{4} \left[ 4p_1 + 1 - 2p_1 + \left[ p_1 \frac{p_1 - q_1^2}{q_1} \right] \right] (z_3 - z_2)
= z_2 + \frac{1}{2} \left[ \frac{1}{2} + p_1 + \frac{1}{2} \frac{p_1}{q_1} = \frac{p_2^2 + q_2^2}{q_1^2} + 2q_1 \right] (z_3 - z_2). \quad (11.6.19)

This is the same as (11.6.16) and so \( z_{16}^{(ii)} = z_{16}^{(ii)} \).

The reason we took the particular foot of a perpendicular \( Z_8 \) is it simplify the calculations a little, but the result holds just as well for the feet of the perpendiculars \( Z_9 \) and \( Z_{10} \) as well. For we can give the simplifying to both of these as well as
follows. Starting with our usual notation \( z_1 = z_2 + (p_1 + iq_1)(z_3 - z_2) \) let us seek a corresponding relationship \( z_3 = z_1 + (p_3 + iq_3)(z_2 - z_1) \) based on the same triangle. Then we have

\[
(p_3 + q_3 t - 1)z_1 = -z_3 + (p_3 + iq_3)z_2 = (p_3 + iq_3 - 1)z_2 - (z_3 - z_2),
\]

\[
z_1 = z_2 + \frac{-1}{p_3 + q_3 t - 1} (z_3 - z_2) = z_2 + (p_1 + q_1 t)(z_3 - z_2),
\]

\[
p_1 + q_1 t = \frac{-1}{p_3 + q_3 t - 1},
\]

\[
p_3 + q_3 t - 1 = \frac{-1}{p_1 + q_1 t}, \quad \frac{p_1 - q_1 t}{p_1 - q_1 t} = \frac{-p_1 + q_1 t}{p_1^2 + q_1^2}
\]

\[
p_3 - 1 = \frac{-p_1}{p_1^2 + q_1^2},
\]

\[
q_3 = \frac{p_1}{p_1^2 + q_1^2},
\]

\[
p_3 = 1 - \frac{p_1}{p_1^2 + q_1^2} = \frac{p_1^2 + q_1^2 - p_1}{p_1^2 + q_1^2}.
\]  

(11.6.20)

### 11.6.11 The nine-point circle

We continue with the situation in 11.6.10 where we identified three further points which lie on the circumcircle of the triangle \([Z_4, Z_5, Z_6]\) with vertices the midpoints \(Z_4, Z_5\) and \(Z_6\) of the sides \([Z_2, Z_3], [Z_3, Z_1], [Z_1, Z_2]\), respectively, of the original triangle \(Z_1, Z_2, Z_3\). In this subsection we identify three other points which lie on this circumcircle. Let \(Z_{17}\) be the mid-point of the orthocentre and the vertex \(Z_1\) in the original triangle, \(Z_{18}\) be the mid-point of the orthocentre and the vertex \(Z_2\), and \(Z_{19}\) be the mid-point of the orthocentre and the vertex \(Z_3\). We seek the circumcentre of the triangle \([Z_4, Z_8, Z_{18}]\).
Now \( z_4 = z_2 + \frac{1}{2} (z_3 - z_2), \) \( z_8 = z_2 + p_1(z_3 - z_2), \) and by the formula in 11.6.5 for the orthocentre, \( z_{11} = z_2 + \frac{p_1}{2} \left( 1 - \frac{p_1 - 1}{q_4} t \right) (z_3 - z_2). \) From these we have that

\[
z_{18} = \frac{1}{2} [z_2 + z_2 + p_1 \left( 1 - \frac{p_1 - 1}{q_1} t \right) (z_3 - z_2)] = z_2 + \frac{1}{2} p_1 (1 - \frac{p_1 - 1}{q_1} t) (z_3 - z_2).
\]

We let \( Z_{16}^{(iii)} \) be the circumcentre of the triangle \([Z_4, Z_8, Z_{18}]\) and for the present write

\[
z_4 = z_8 + (p_4 + iq_4)(z_{18} - z_8) = (1 - p_4 - iq_4)z_8 + (p_4 + iq_4)z_{18} = (1 - p_4 - iq_4)[z_2 + p_1(z_3 - z_2)] + (p_4 + iq_4)[z_2 + \frac{1}{2} p_1 (1 - \frac{p_1 - 1}{q_1} t)](z_3 - z_2)
\]

\[
= (1 - iq_4 + iq_4)z_2 + [(1 - p_4 - iq_4)p_1 + (p_4 + iq_4)\frac{1}{2} p_1 (1 - \frac{p_1 - 1}{q_1} t)](z_3 - z_2)
\]

\[
= z_2 + p_1 \left[ 1 - p_4 - iq_4 + \frac{1}{2} (p_4 + iq_4) [1 - \frac{p_1 - 1}{q_1} t] \right] (z_3 - z_2)
\]

\[
= z_2 + p_1 \left[ 1 - p_4 - q_4 t + \frac{1}{2} (p_4 + q_4 t) - \frac{1}{2} (p_4 + q_4 t) \frac{p_1 - 1}{q_1} t \right] (z_3 - z_2)
\]

\[
= z_2 + p_1 \left[ 1 - \frac{1}{2} p_4 - \frac{1}{2} q_4 t - \frac{1}{2} p_4 \frac{p_1 - 1}{q_1} t + \frac{1}{2} q_4 \frac{p_1 - 1}{q_1} t \right] (z_3 - z_2)
\]

\[
= z_2 + p_1 \left[ 1 - \frac{1}{2} p_4 + \frac{1}{2} q_4 \frac{p_1 - 1}{q_1} t - \frac{1}{2} (q_4 + p_4 \frac{p_1 - 1}{q_1} t) \right] (z_3 - z_2)
\]

\[
= z_2 + \frac{1}{2} (z_3 - z_2).
\]

Hence

\[
p_1 \left[ 1 - \frac{1}{2} p_4 + \frac{1}{2} q_4 \frac{p_1 - 1}{q_1} t - \frac{1}{2} (q_4 + p_4 \frac{p_1 - 1}{q_1} t) \right] = \frac{1}{2}
\]

so that

\[
q_4 + p_4 \frac{p_1 - 1}{q_1} = 0, p_1 \left[ 1 - \frac{1}{2} p_4 + \frac{1}{2} q_4 \frac{p_1 - 1}{q_1} t \right] = \frac{1}{2}.
\]

Then \( q_4 = -\frac{p_1 - 1}{q_1} p_4 \) and

\[
-\frac{1}{2} p_1 p_4 + \frac{1}{2} \frac{p_1 - 1}{q_1} q_4 = \frac{1}{2} - p_1, -p_4 + \frac{p_1 - 1}{q_1} q_4 = (\frac{1}{2} - p_1) \frac{2}{p_1}, \\
-p_4 - \frac{p_1 - 1}{q_1} \frac{p_1 - 1}{q_1} p_4 = \frac{1}{p_1} - 2, -p_4 \left[ 1 + \frac{(p_1 - 1)^2}{q_1^2} \right] = \frac{1}{2} - \frac{2 p_1}{p_1},
\]

\[
p_4 = \frac{(2 p_1 - 1) q_1^2}{p_1 (q_1^2 + (p_1 - 1)^2)},
\]

\[
q_4 = -\frac{p_1 - 1}{q_1} \frac{2 p_1 - 1}{p_1} \frac{q_1^2}{[q_1^2 + (p_1 - 1)^2]} \frac{q_4^4}{q_1^2 + (p_1 - 1)^2},
\]

\[
p_4^2 + q_4^2 = \left[ 1 + \left( \frac{p_1 - 1}{p_1} \right)^2 \right] \frac{(2 p_1 - 1)^2}{p_1^2} \frac{q_4^4}{[q_1^2 + (p_1 - 1)^2]}.
\]
Then

\[ p_4^2 + q_4^2 = p_4^2 + \left( \frac{p_1 - 1}{q_1} \right)^2 p_4^2, \]

\[ \frac{p_4^2 + q_4^2}{q_4} = \frac{p_4^2}{q_4} \left( 1 + \left( \frac{p_1 - 1}{q_1} \right)^2 \right) \]

\[ = p_4 \cdot \frac{-q_1}{p_1 - 1} \left( 1 + \left( \frac{p_1 - 1}{q_1} \right)^2 \right) \]

\[ = \frac{2p_1 - 1}{p_1} \cdot \frac{1}{1 + \frac{(p_1 - 1)^2}{p_1 - 1}} \cdot \frac{-q_1}{p_1 - 1} \left( 1 + \left( \frac{p_1 - 1}{q_1} \right)^2 \right) \]

\[ = -\frac{2p_1 - 1}{p_1} \cdot \frac{q_1}{p_1 - 1}. \]

By (11.6.4) the circumcentre \( Z_{16}^{(iii)} \) of \([Z_4, Z_8, Z_{18}]\) where

\[ z_4 = z_8 + (p_4 + q_4 t)(z_{18} - z_8) \]

is given by

\[ z_{16}^{(iii)} = z_8 + \frac{1}{2} \left[ 1 + \frac{p_4^2 + q_4^2}{q_4} t - \frac{p_4}{q_4} t \right] (z_{18} - z_8) \]

\[ = z_8 + \frac{1}{2} \left[ 1 + \frac{p_4^2 \left( 1 + \frac{(p_1 - 1)^2}{q_1^2} \right)}{q_4} t + \frac{q_1}{p_1 - 1} t \right] (z_{18} - z_8) \]

\[ = z_8 + \frac{1}{2} \left[ 1 + \frac{-q_1}{p_1 - 1} \left( 1 + \frac{(p_1 - 1)^2}{q_1^2} \right) t + \frac{q_1}{p_1 - 1} t \right] (z_{18} - z_8) \]

\[ = z_8 + \frac{1}{2} \left[ 1 - \frac{2p_1 - 1}{p_1} \cdot \frac{q_1}{p_1 - 1} t + \frac{q_1}{p_1 - 1} t + \frac{q_1}{p_1 - 1} t \right] (z_{18} - z_8) \]

\[ = z_8 + \frac{1}{2} \left[ 1 + \frac{q_1}{p_1 - 1} \left( -\frac{2p_1 - 1}{p_1} + 1 \right) t \right] (z_{24} - z_8) \]

\[ = z_8 + \frac{1}{2} \left[ 1 - \frac{q_1}{p_1} t \right] (z_{18} - z_8). \]

Continuing from this we have
\[ z^{(iii)}_{16} = z_2 + p_1(z_3 - z_2) + \frac{1}{2}(1 - \frac{q_1}{p_1}t)[z_2 + \frac{1}{2}p_1(1 - \frac{p_1 - 1}{q_1}t) - z_2 - p_1](z_3 - z_2) \]
\[ = z_2 + p_1(z_3 - z_2) + \frac{1}{2}(1 - \frac{q_1}{p_1}t)[\frac{1}{2}p_1(1 - \frac{p_1 - 1}{q_1}t) - p_1](z_3 - z_2) \]
\[ = z_2 + \left[p_1 + \frac{1}{2}(1 - \frac{q_1}{p_1}t)[\frac{1}{2}p_1(1 - \frac{p_1 - 1}{q_1}t) - p_1]\right](z_3 - z_2) \]
\[ = z_2 + p_1 \left[1 + \frac{1}{2}(1 - \frac{q_1}{p_1}t)[-\frac{1}{2} - \frac{1}{2} \frac{p_1 - 1}{q_1}t]\right](z_3 - z_2) \]
\[ = z_2 + p_1 \left[1 - \frac{1}{4}(1 - \frac{q_1}{p_1}t)(1 + \frac{p_1 - 1}{q_1}t)\right](z_3 - z_2) \]
\[ = z_2 + p_1 \left[1 - \frac{1}{4}[1 + \frac{q_1 p_1 - 1}{p_1 q_1} + (\frac{p_1 - 1}{q_1} - \frac{q_1}{p_1})t]\right](z_3 - z_2) \]
\[ = z_2 + p_1 \left[1 - \frac{1}{4}[1 + \frac{p_1 - 1}{p_1} + \frac{p_1^2 - p_1 - q_1^2}{p_1 q_1}t]\right](z_3 - z_2) \]
\[ = z_2 + p_1 \left[1 - \frac{2}{4}p_1 - \frac{1}{4}p_1^2 + \frac{q_1^2 - p_1 - q_1^2}{p_1 q_1}t\right](z_3 - z_2) \]
\[ = z_2 + \left[\frac{1}{4} + \frac{1}{2}p_1 - \frac{1}{4}\frac{p_1^2 + q_1^2}{q_1} - \frac{p_1}{q_1} - 2q_1t\right](z_3 - z_2) \]
\[ = z_2 + \left[\frac{1}{4} + 2p_1 - \frac{p_1^2 + q_1^2}{q_1} + \frac{p_1}{q_1} + 2q_1t\right](z_3 - z_2). \]

By (11.6.16) this is the same as that for \(Z_{16}'\). The same argument applies to \(Z_{17}\) and \(Z_{19}\).

Thus we have identified six extra points on the circle which passes through the mid-points of the sides of the original triangle, which is named from this property.

There is an interesting article on this circle in Wikipedia. By a coincidence we have \(Z_{10} = Z_{18}\) in our diagram.

### 11.6.12 Parametric equations of lines.

For general distinct points \(Z_4\) and \(Z_5\) and general \(Z \in Z_4Z_5\) we have that

\[ z_4 = z_2 + (p_4 + q_4t)(z_3 - z_2), \]
\[ z_5 = z_2 + (p_5 + q_5t)(z_3 - z_2), \]
\[ z = z_2 + (p + qt)(z_3 - z_2), \]

and then

\[ z = z_4 + s(z_5 - z_4) = (1 - s)z_4 + sz_5, \quad (s \in \mathbb{R}) \]
\[ = (1 - s)[z_2 + (p_4 + q_4t)(z_3 - z_2)] + s[z_2 + (p_5 + q_5t)(z_3 - z_2)] \]
\[ = (1 - s + s)z_2 + [(1 - s)(p_4 + q_4t) + s(p_5 + q_5t)](z_3 - z_2) \]
\[ = z_2 + \{(1 - s)p_4 + sp_5 + [(1 - s)q_4 + sq_5]t\}(z_3 - z_2). \]
11.7 SOME WELL-KNOWN THEOREMS

NOTE. The advantage of mobile coordinates is that they located a point with respect to a triangle using just two instead of three numbers and they also behave like re-scaled Cartesian coordinates. None the less they can lead to unwieldy expressions as in this section and it is a good idea when possible to check the algebraic manipulations using a computer software programme.

11.7.1 Feuerbach’s theorem, 1822

We recall that the nine-point circle has radius-length equal to the distance from $Z'_{16}$ to $Z_4$. From the formula

$$z'_{16} - z_4 = \frac{1}{2}(p_1 + q_1i) \left[ 1 - \frac{i}{2q_1} (p_1 - 1 - q_1i) \right] (z_3 - z_2)$$

$$= \frac{1}{4q_1} (p_1 + q_1i)[q_1 + (1-p_1)i](z_3 - z_2)$$

we note that

$$|z'_{16} - z_4| = \frac{a}{4|q_1|} |p_1 + q_1i||q_1 + (1-p_1)i| = \frac{a}{4|q_1|} \sqrt{p_1^2 + q_1^2} \sqrt{(p_1 - 1)^2 + q_1^2},$$

and so this is the radius-length of the nine-point circle. We denote this radius length by $r_1$.

Our formula in 11.6.5 for the incentre of a triangle is very awkward to apply because of the complicated term in the denominator. However by eliminating the surds in the denominator in two steps, by multiplying above and below by a conjugate surd of the denominator, we obtain the more convenient formulation that

$$\frac{p_1 + \sqrt{p_1^2 + q_1^2}}{1 + \sqrt{p_1^2 + q_1^2} + \sqrt{(p_1 - 1)^2 + q_1^2}} = \frac{1}{2} + \frac{1}{2} \sqrt{p_1^2 + q_1^2} - \frac{1}{2} \sqrt{(p_1 - 1)^2 + q_1^2}. \quad (11.7.1)$$

In fact once we know the form of this we can establish it more directly and easily by noting that

$$\frac{1}{2} \left[ 1 + \sqrt{p_1^2 + q_1^2} + \sqrt{(p_1 - 1)^2 + q_1^2} \right] \left[ 1 + \sqrt{p_1^2 + q_1^2} - \sqrt{(p_1 - 1)^2 + q_1^2} \right]$$

$$= \frac{1}{2} \left[ (1 + \sqrt{p_1^2 + q_1^2})^2 - ((p_1 - 1)^2 + q_1^2) \right]$$

$$= p_1 + \sqrt{p_1^2 + q_1^2}.$$ 

We note that the right-hand side in (11.7.1) must be positive.
Recalling from 11.6.5 that the incentre $Z_{15}$ has complex coordinate

$$z_{15} = z_2 + \frac{p_1 + \sqrt{p_1^2 + q_1^2 + q_{11}}}{1 + \sqrt{p_1^2 + q_1^2 + (p_1 - 1)^2 + q_1^2}}(z_3 - z_2),$$

we re-write this as

$$z_{15} - z_2 = \frac{1}{2} \left[ 1 + \sqrt{p_1^2 + q_1^2 - (p_1 - 1)^2 + q_1^2} \right] \left[ 1 + \frac{q_{11}}{p_1 + \sqrt{p_1^2 + q_1^2}} \right] (z_3 - z_2)$$

$$= \frac{1}{2q_1} \left[ 1 + \sqrt{p_1^2 + q_1^2 - (p_1 - 1)^2 + q_1^2} \right] \left[ q_1 + \left( \sqrt{p_1^2 + q_1^2 - p_1} \right) i \right] (z_3 - z_2).$$

From this, the foot $Z_{20}$ of the perpendicular from the incentre $Z_{15}$ to the line $Z_2Z_3$ has complex coordinate

$$z_{20} = z_2 + \frac{1}{2q_1} \left[ 1 + \sqrt{p_1^2 + q_1^2 - (p_1 - 1)^2 + q_1^2} \right] q_1 (z_3 - z_2) \quad (11.7.2)$$

and so the length of radius of the incircle is equal to

$$\frac{a}{2} \left[ 1 + \sqrt{p_1^2 + q_1^2 - (p_1 - 1)^2 + q_1^2} \right] \left[ \sqrt{p_1^2 + q_1^2 - p_1} \right]. \quad (11.7.3)$$

We denote this radius length by $r_2$.

With these preparatory results, we can now show that the nine-point circle and the incircle meet at just one point and they have a common tangent there.

Figure 11.17. Feuerbach’s theorem.

It is clear from diagrams that $r_1 > r_2$ and known from earlier proofs. We will first give the proof in this case and then a proof that $r_4 \geq r_1$ cannot occur.

The half-line $[Z'_{16}, Z_{15}$ has points $Z = Z'_{16} + s(Z_{15} - Z'_{16})$ where $s \geq 0$ and will meet the nine-point circle at a point

$$z_{21} = z'_{16} + \frac{r_1}{|z_{15} - z'_{16}|}(z_{15} - z'_{16}).$$
It will also meet the nine-point circle at the point

\[ z_{22} = z'_{16} - \frac{r_1}{|z_{15} - z'_{16}|}(z_{15} - z'_{16}). \]

The mid-point of these two points is the centre \( Z'_{16} \) of the nine-point circle and so \([Z_{21}, Z_{22}]\) is a diameter of this nine-point circle.

Similarly the half-line \([Z_{15}, Z'_{16}]\) has points \( Z = Z_{15} - t(Z'_{16} - Z_{15}) \) and meets the incircle at the point

\[ z = z_{15} - \frac{r_2}{|z'_{16} - z_{15}|}(z'_{16} - z_{15}). \]

Then clearly this is the point \( Z_{21} \) again and the corresponding point

\[ z_{24} = z_{15} + \frac{r_2}{|z'_{16} - z_{15}|}(z'_{16} - z_{15}) \]

will be a diametrically opposite point on the incircle. Then the nine-point circle and the incircle have a common tangent at the point \( Z_{21} \).

It is clear from elementary geometry that, if two circles touch at just one point, the centres of the two triangle and the point of tangency must be collinear. The following is a skeleton picture of a possible situation.

![Figure 11.18.](image)

Now we turn to the supposition that \( r_2 \geq r_1 \). We first suppose that \( r_2 > r_1 \). We treat the incircle as above and take the point

\[ z_{24} = z_{15} + \frac{r_2}{|z'_{16} - z_{15}|}(z'_{16} - z_{15}). \]

Then \( Z_{24} \) is a point on the incircle and the point

\[ z_{25} = z_{15} - \frac{r_2}{|z'_{16} - z_{15}|}(z'_{16} - z_{15}). \]

is such that \([z_{24}, z_{25}]\) is a diameter of the incircle.
For the nine-point circle we take the point $Z_{26}$ such that

$$z_{26} = z'_{16} + \frac{r_1}{|z_{15} - z'_{16}|}(z'_{16} - z_{15}),$$

Then $Z_{26}$ is a point of the line $Z'_{16}Z_{15}$ which lies on the nine-points circle and the corresponding point

$$z_{27} = z'_{16} - \frac{r_1}{|z_{15} - z'_{16}|}(z'_{16} - z_{15}),$$

also lies on the nine-point circle for which $[z_{26}, z_{27}]$ is a diameter. But in fact the points $Z_{24}$ and $Z_{26}$ coincide and we then have the situation that $Z_{27} \in [Z_{24}, Z_{25}]$.

Thus we have that the incircle has diameter $[Z_{24}, Z_{25}]$ and the nine-point circle has diameter $[z_{24}, z_{27}]$ and $[z_{24}, z_{27}] \subset [z_{24}, z_{25}]$. It follows that the nine-point circle lies inside or on the incircle. But the incircle lies inside or on the triangle $[Z_1Z_2Z_3]$ and it follows that the nine-points circle lies inside or on the triangle. But this yields a contradiction as the nine-points circle passes through the mid-points $Z_4, Z_5, Z_6$ of the sides of this triangle.

There remains the case when $r_2 = r_1$ and now we must have $Z'_{16} = Z_{15}$ and the nine-points circle must coincide with the incircle. In this case the two circles do not meet in a unique point.

This result is known as the basic form of Feuerbach’s theorem.

### 11.7.2 The Wallace-Simson line, 1797

We take a triangle $[Z_1, Z_2, Z_3]$ and for a point $Z$ let $W_1, W_2, W_3$ be the feet of the perpendiculars from $Z$ to the side-lines $Z_2Z_3, Z_3Z_1, Z_1Z_2$, respectively.

![Figure 11.19(a). A right sensed duo-angle.](image)

![Figure 11.19(b). A Simson-Wallace line.](image)

Using notation like that in 11.6.3?, we suppose that $z_1 - z_2 = (p_1 + q_1t)(z_3 - z_2)$, $z - z_2 = (p + qt)(z_3 - z_2)$. Then $z = z_2 + p(z_3 - z_2) + qt(z_3 - z_2)$, and so $w_1 = z_2 + p(z_3 - z_2)$. Next $w_2 = z_3 + s(z_1 - z_3)$, for some $s \in \mathbb{R}$. Hence $z - w_2 = (p - 1 + qt)(z_3 - z_2)$.
s(z_1 - z_3). But z_1 - z_3 = (p_1 - 1 + q_1 i)(z_3 - z_2), so z_3 - z_2 = \frac{1}{p_1 - 1 + q_1 i}(z_1 - z_3). On inserting this, we have that \(z - w_2 = \left(\frac{p - 1 + q_1 i}{p_1 - 1 + q_1 i} - s\right)(z_1 - z_3)\). We wish the coefficient of \(z_1 - z_3\) to be purely imaginary, and so take \(s = \frac{(p-1)(p_1-1)+qq_1}{(p_1-1)^2+q_1^2}\). Hence \(w_2 = z_3 + \frac{(p-1)(p_1-1)+qq_1}{(p_1-1)^2+q_1^2}(z_1 - z_3)\).

Thirdly, \(w_3 = z_2 + t(z_1 - z_2)\), for some \(t \in \mathbb{R}\). Hence \(z - w_3 = (p + qi)(z_3 - z_2) - t(z_1 - z_2)\). But \(z_3 - z_2 = \frac{1}{p_1 + qi t}(z_1 - z_2)\) and so \(z - w_3 = \left(\frac{p + qi t}{p_1 + qi t} - t\right)(z_1 - z_2)\). We choose \(t\) so that the coefficient of \(z_1 - z_2\) is purely imaginary. Thus \(t = \frac{pp_1 + qq_1}{p_1^2 + q_1^2}\), which yields \(w_3 = z_2 + \frac{pp_1 + qq_1}{p_1^2 + q_1^2}(z_1 - z_2)\).

From these expressions for \(w_1, w_2, w_3\) we note that

\[
\frac{w_2 - w_1}{w_3 - w_1} = \frac{z_3 - z_2 + \frac{(p-1)(p_1-1)+qq_1}{(p_1-1)^2+q_1^2}(z_1 - z_3) - p(z_3 - z_2)}{p (z_3 - z_2) - p(z_3 - z_2)} = \frac{1 - p + \frac{(p-1)(p_1-1)+qq_1}{(p_1-1)^2+q_1^2}(p_1 - 1 + qi t) - p}{p_1 + q_1 i (p_1 + q_1 i t) - p}.
\]

The real part of this has numerator \((p_1^2 + q_1^2 - p_1)(p^2 + q_2^2) - (p_1^2 + q_1^2 - p_1)p + q_1 q\), and the imaginary part has numerator \(q_1 (p^2 + q_2^2) - q_1 p - (p_1^2 + q_1^2 - p_1) q\). If \(\theta = \angle \vartheta W_3 W_1 W_2\) then for \(\theta\) to have a constant magnitude it is necessary and sufficient that

\[
q_1 (p^2 + q_2^2) - q_1 p - (p_1^2 + q_1^2 - p_1) q = k[(p_1^2 + q_1^2 - p_1)(p^2 + q_2^2) - (p_1^2 + q_1^2 - p_1)p + q_1 q].
\]

This can be re-written as

\[
a^2 \left[ \left( p - \frac{1}{2} \right)^2 + \left( q - \frac{p_1^2 + q_1^2 - p_1}{2q_1} \right)^2 \right] - \frac{a^2}{4} \left[ 1 + \frac{(p_1^2 + q_1^2 - p_1)^2}{q_1^2} \right] = k \left\{ a^2 \left[ \left( p - \frac{1}{2} \right)^2 + \left( q + \frac{q_1}{2(p_1^2 + q_1^2 - p_1)} \right)^2 \right] - \frac{a^2}{4} \left[ 1 + \frac{q_1^2}{(p_1^2 + q_1^2 - p_1)^2} \right] \right\}.
\]

On using 11.6.1 we infer that as \(k\) varies this gives the family of coaxial circles which pass through \(Z_2\) and \(Z_3\).

For \(W_1, W_2, W_3\) to be collinear, it is necessary and sufficient that the expression be real. On equating its imaginary part to 0 we obtain \(q_1 (p^2 + q_2^2) - q_1 p - (p_1^2 + q_1^2 - p_1) q = 0\). On writing this as \(\frac{p^2 + q_2^2 - p}{q} = \frac{p_1^2 + q_1^2 - p_1}{q_1}\), we note from the formula for a circumcentre in 11.6.4? that it holds when \(Z\) lies on the circumcircle of the triangle\([Z_1, Z_2, Z_3]\).

This latter result is due to WALLACE, but SIMSON’s name has for a long time been associated with it.
11.7.3 The incentre on the Euler line of a triangle

We suppose that we have the mobile coordinates \(z_1 - z_2 = (p_1 + q_1 i)(z_3 - z_2)\), where \(p_1\) and \(q_1\) are real numbers and \(q_1 \neq 0\). Then \(z_1 - z_3 = (p_1 - 1 + q_1 i)(z_3 - z_2)\), and as in 11.6.3 we have

\[
\frac{z_1 - z_2}{z_3 - z_2} = p_1 + qi = \frac{c}{a} \text{cis} \beta, \quad \frac{z_2 - z_3}{z_1 - z_3} = \frac{1 - p_1 + qi}{(1 - p_1)^2 + q_1^2} = \frac{a}{b} \text{cis} \gamma,
\]

\[
\frac{z_3 - z_1}{z_2 - z_1} = \frac{p_1 - 1 + qi}{p_1 + qi} = \frac{b}{c} \text{cis} \alpha,
\]

where we are using our standard notation. Then \(p_1^2 + q_1^2 = \frac{c^2}{a^2}\), \((1 - p_1)^2 + q_1^2 = \frac{b^2}{a^2}\).

We recall that the orthocentre, centroid and incentre have mobile coordinates \(p_1 + \frac{p_1(1 - p_1)}{q_1} i, \frac{p_1 + 1}{3} + \frac{q_1}{3} i\), \(\frac{p_1 + \sqrt{p_1^2 + q_1^2 + q_1^2}}{1 + \sqrt{p_1^2 + q_1^2 + (1 - p_1)^2 + q_1^2}}\) respectively.

Now \(1 - 2p_1 = \frac{b^2 - c^2}{2a^2}\), \(p_1 = \frac{c^2 + a^2 - b^2}{2a^2}\), \(1 - p_1 = \frac{a^2 + b^2 - c^2}{2a^2}\), \(p_1 + 1 = \frac{c^2 + a^2 - b^2 + 2a^2}{2a^2}\).

Moreover

\[
q_1^2 = \frac{c^2 - p_1^2}{a^2} = \frac{c^2 - (\frac{c^2 + a^2 - b^2}{2a^2})^2}{a^2} = -\frac{(c^2 + a^2 - b^2)^2 - 4c^2 a^2}{4a^4},
\]

while

\[
p_1 + \sqrt{p_1^2 + q_1^2} = \frac{c^2 + a^2 - b^2}{2a^2} + \frac{c}{a} = \frac{(c + a)^2 - b^2}{2a^2},
\]

\[
1 + \frac{p_1^2 + q_1^2}{1 + \sqrt{p_1^2 + q_1^2 + (1 - p_1)^2 + q_1^2}} = 1 + \frac{c}{a} + \frac{b}{a} = \frac{a + b + c}{a},
\]

so that

\[
\frac{p_1 + \sqrt{p_1^2 + q_1^2}}{1 + \sqrt{p_1^2 + q_1^2 + (1 - p_1)^2 + q_1^2}} = \frac{(c + a)^2 - b^2}{2a(a + b + c)} = \frac{c + a - b}{2a},
\]

\[
\frac{q_1^2}{1 + \sqrt{p_1^2 + q_1^2 + (1 - p_1)^2 + q_1^2}} = -1 \frac{[(c + a)^2 - b^2][(c - a)^2 - b^2]}{4a^3 (a + b + c)} = \frac{1}{4a^3} (c + a - b)[(c - a)^2 - b^2].
\]

The determinant for collinearity, on multiplying the middle column by \(q_1\), is

\[
\begin{vmatrix}
\frac{c^2 + a^2 - b^2}{2a^2} & \frac{(c^2 + a^2 - b^2)(a^2 + b^2 - c^2)}{6a^4} & 1 \\
\frac{c^2 + a^2 - b^2 + 2a^2}{6a^4} & \frac{4q_1^2}{[(c + a)^2 - b^2]} & 1 \\
\frac{c + a - b}{2a} & -\frac{[(c + a)^2 - b^2][12a^4]}{4a^3} & 1
\end{vmatrix}
\]

Sec. 11.7 Some well-known theorems
and this is a non-zero multiple of

\[
\begin{vmatrix}
  c^2 + a^2 - b^2 & (c^2 + a^2 - b^2)(a^2 + b^2 - c^2) & 1 \\
  c^2 + a^2 - b^2 + 2a^2 & -[(c + a)^2 - b^2][(c - a)^2 - b^2] & 3 \\
  a(c + a - b) & -a(c + a - b)[(c - a)^2 - b^2] & 1
\end{vmatrix}
\]

the value of which is \(4(ca^5 - c^3a^3 - ba^5 + a^3b^3 + c^3ba^2 - b^3ca^2)\). This factorizes as

\[4a^2(b - c)(c - a)(a + b + c)\]

and so the incentre lies on the Euler line if and only if the triangle is isosceles.

11.7.4 Miquel’s theorem, 1838

Let \(Z_1, Z_2, Z_3\) be non-collinear points, and \(Z_4 \in Z_2Z_3\), \(Z_5 \in Z_3Z_1\), \(Z_6 \in Z_1Z_2\) be distinct from \(Z_1, Z_2\) and \(Z_3\). Let \(\mathcal{C}_1, \mathcal{C}_2, \mathcal{C}_3\) be the circumcircles of \([Z_1, Z_5, Z_6]\), \([Z_2, Z_6, Z_4]\), \([Z_3, Z_4, Z_5]\), respectively. Then \(\mathcal{C}_1, \mathcal{C}_2, \mathcal{C}_3\) have a point in common.

**Proof.** Suppose that these circles have centres the points \(W_1, W_2, W_3\), respectively.

We first assume that \(\mathcal{C}_2\) and \(\mathcal{C}_3\) meet at a second point \(Z_7 \neq Z_4\). If \(Z_7 = Z_6\) the result is trivially true, so we may exclude that case. As \(Z_1, Z_2, Z_6\) are collinear, we have \(z_1 - z_6 = -\nu(z_2 - z_6)\), for some non-zero \(\nu\) in \(\mathbb{R}\). As \(Z_2, Z_4, Z_6, Z_7\) are concyclic, by 10.9.3 we have \(\frac{z_2 - z_6}{z_7 - z_6} = \frac{z_2 - z_4}{z_7 - z_4}\), for some non-zero \(\rho\) in \(\mathbb{R}\). As \(Z_2, Z_3, Z_4\) are collinear, we have \(z_2 - z_4 = -\lambda(z_3 - z_4)\), for some non-zero \(\lambda\) in \(\mathbb{R}\). As \(Z_3, Z_4, Z_5, Z_7\) are concyclic, we have \(\frac{z_3 - z_4}{z_7 - z_4} = \frac{z_3 - z_5}{z_7 - z_5}\), for some non-zero \(\sigma\) in \(\mathbb{R}\). On combining these we have

\[
\frac{z_1 - z_6}{z_7 - z_6} = \nu\rho\lambda\sigma\frac{z_2 - z_6}{z_7 - z_6}.
\]

It follows by 10.9.3 that \(Z_1, Z_5, Z_6, Z_7\) are concyclic.

We suppose secondly that \(\mathcal{C}_2\) and \(\mathcal{C}_3\) have a common tangent at \(Z_2\). It is convenient to suppose that \(z_1 = z_2 + (p_1 + iq_1)(z_3 - z_2)\) and \(w_2 = z_2 + (p + iq)(z_3 - z_2)\). Then the foot \(Z_7\) of the perpendicular from \(W_2\) to \(Z_2Z_3\) has complex coordinate \(z_7 = z_2 + p(z_3 - z_2)\), and hence \(z_4 = z_2 + 2p(z_3 - z_2)\). Then the mid-point \(Z_8\) of \(Z_3\) and \(Z_4\) has complex coordinate \(z_8 = z_2 + (p + \frac{1}{2})(z_3 - z_2)\). It follows that for the centre \(W_3\) of \(\mathcal{C}_3\)
we have \( w_3 = z_2 + (p + 1/2 + iq')(z_3 - z_2) \), for some real number \( q' \). But \( Z_4, W_2, W_3 \) are collinear, so that

\[
\begin{vmatrix}
2p & 0 & 1 \\
p & q & 1 \\
p + 1/2 & q' & 1
\end{vmatrix} = 0,
\]

and from this \( q' = \frac{p - 1/2}{p} q_1 (z_3 - z_2) \). Hence \( w_3 = z_2 + \left( p + \frac{1}{2} + \frac{p - 1/2}{p} q_1 \right) (z_3 - z_2) \). From this \( w_3 - z_3 = \frac{p - 1/2}{p} (p + q_1) (z_3 - z_2) \), and since \( z_3 - z_2 = \frac{1}{p_1 - 1 + iq_1} (z_1 - z_3) \), we have \( w_3 = z_3 + \frac{p - 1/2}{p} \frac{p(p_1 - 1) + q_1}{(p_1 - 1)^2 + q_1^2} (z_1 - z_3) \). Thus if \( Z_9 \) is the foot of the perpendicular from \( W_3 \) to \( Z_3 Z_1 \), we have \( Z_9 = z_3 + \frac{p - 1/2}{p} \frac{p(p_1 - 1) + q_1}{(p_1 - 1)^2 + q_1^2} (z_1 - z_3) \), and so

\[
z_5 = z_3 + 2p - 1 \frac{p(p_1 - 1) + q_1}{(p_1 - 1)^2 + q_1^2} (z_1 - z_3).
\]

Similarly \( w_2 = z_2 + (p + iq) (z_3 - z_2) \), \( z_3 - z_2 = \frac{1}{p_1 + iq_1} (z_1 - z_2) \), and so \( w_2 = z_2 + \frac{p + iq}{p_1 + iq_1} (z_1 - z_2) \). It follows that for the foot \( Z_{10} \) of the perpendicular from \( W_2 \) to \( Z_1 Z_2 \) we have \( z_{10} = z_2 + \frac{pp_1 + q_1}{p_1^2 + q_1^2} (z_1 - z_2) \), and so \( z_6 = z_2 + 2 \frac{pp_1 + q_1}{p_1^2 + q_1^2} (z_1 - z_2) \).

We have

\[
z_1 - z_5 = \left[ 1 - 2p - 1 \frac{1}{p} \frac{p(p_1 - 1) + q_1}{(p_1 - 1)^2 + q_1^2} \right] (z_1 - z_3),
\]

\[
z_1 - z_6 = \left[ 1 - 2 \frac{pp_1 + q_1}{p_1^2 + q_1^2} \right] (z_1 - z_2),
\]

\[
z_4 - z_5 = 2p(z_3 - z_2) - 2 \frac{pp_1 + q_1}{p_1^2 + q_1^2} (z_1 - z_2)
\]

\[
= 2 \left[ p - \frac{pp_1 + q_1}{p_1^2 + q_1^2} (p_1 + iq_1) \right] (z_3 - z_2),
\]

\[
z_4 - z_5 = \left[ (2p - 1)(z_3 - z_2) - 2p - 1 \frac{p(p_1 - 1) + q_1}{(p_1 - 1)^2 + q_1^2} (z_1 - z_3) \right]
\]

\[
= \frac{2p - 1}{p} \left[ p - \frac{p(p_1 - 1) + q_1}{(p_1 - 1)^2 + q_1^2} (p_1 + iq_1) \right] (z_3 - z_2).
\]

As \( z_1 - z_2 = (p_1 + iq_1) (z_3 - z_2) \), from these combined we have that \( \frac{(z_1 - z_5)(z_4 - z_6)}{(z_1 - z_6)(z_4 - z_5)} \) is a real multiple of

\[
\frac{\left[ p - \frac{pp_1 + q_1}{p_1^2 + q_1^2} (p_1 + iq_1) \right] (p_1 - 1 + iq_1)}{\left[ p - \frac{p(p_1 - 1) + q_1}{(p_1 - 1)^2 + q_1^2} (p_1 + 1 + iq_1) \right] (p_1 + iq_1)} = \frac{\left[ p - \frac{pp_1 + q_1}{p_1 - 1 + iq_1} \right] (p_1 - 1 + iq_1)}{\left[ p - \frac{p(p_1 - 1) + q_1}{p_1 - 1 - iq_1} \right] (p_1 + iq_1)}
\]

\[
= -q_1 (ip + q) [(p_1 - 1)^2 + q_1^2]
\]

\[
- q_1 (ip + q) [p_1^2 + q_1^2]
\]

\[
= \frac{(p_1 - 1)^2 + q_1^2}{p_1^2 + q_1^2},
\]

and this is real. It follows that \( Z_1, Z_4, Z_5, Z_6 \) are concyclic. This is known as **Miquel’s theorem**.
11.8 ISOGONAL CONJUGATES

11.8.1 Isogonal conjugates

**Definition.** Given non-collinear points $Z_1, Z_2, Z_3$, we say that half-lines $[Z_1, Z_4]$ and $[Z_1, Z_5]$ are **isogonal conjugates** with respect to the angle-support $\angle Z_2Z_1Z_3$ if the sensed angles $\angleZFZ_2Z_1Z_4$, $\angleZFZ_5Z_1Z_3$, have equal magnitudes.

![Figure 11.21. Isogonal conjugates.](image)

To see how this operates, we first suppose that $Z_4$ and $Z_5$ are both on the line $Z_2Z_3$ and that

$$Z_4 = \frac{1}{1 + \lambda_1}Z_2 + \frac{\lambda_1}{1 + \lambda_1}Z_3, \quad Z_5 = \frac{1}{1 + \lambda_2}Z_2 + \frac{\lambda_2}{1 + \lambda_2}Z_3,$$

for real numbers $\lambda_1$ and $\lambda_2$. We recall that then

$$\frac{Z_2Z_4}{Z_4Z_3} = \lambda_1, \quad \frac{Z_2Z_5}{Z_5Z_3} = \lambda_2.$$  

Then

$$\frac{z_4 - z_1}{z_2 - z_1} \frac{z_3 - z_1}{z_5 - z_1} = \frac{1 + \lambda_1}{1 + \lambda_1} \frac{z_2 + \frac{\lambda_1}{1 + \lambda_1}z_3 - z_1}{z_2 - z_1} \frac{1 + \lambda_2}{1 + \lambda_2} \frac{z_2 + \frac{\lambda_2}{1 + \lambda_2}z_3 - z_1}{z_3 - z_1}$$

is positive and so on multiplying across by $(1 + \lambda_1)(1 + \lambda_2)$

$$\frac{z_2 - z_1 + \lambda_1(z_3 - z_1)}{z_2 - z_1} \frac{z_2 - z_1 + \lambda_2(z_3 - z_1)}{z_3 - z_1} = \frac{z_2 - z_1}{z_3 - z_1} + \lambda_1 \lambda_2 \frac{z_3 - z_1}{z_2 - z_1} + \lambda_1 + \lambda_2$$

is real. On subtracting $\lambda_1 + \lambda_2$ it follows that

$$\frac{z_2 - z_1}{z_3 - z_1} + \lambda_1 \lambda_2 \frac{1}{(z_2 - z_1)/(z_3 - z_1)}$$

is real. We write

$$\frac{z_2 - z_1}{z_3 - z_1} = u + vi, \quad (u, v \in \mathbb{R}),$$
where \( v \neq 0 \) as \( Z_1 \not\in Z_2Z_3 \). With this notation we have that \( u + v + \lambda_1 \lambda_2 \frac{u \cdot v}{u + v} \) is real so that \( v - \lambda_1 \lambda_2 \frac{u \cdot v}{u + v} = 0 \), and hence \( \lambda_1 \lambda_2 = u^2 + v^2 \). We deduce that \( \lambda_1 \lambda_2 = \frac{|Z_1Z_2|^2}{|Z_1Z_3|^2} \).

As \( \lambda_1 \lambda_2 > 0 \), the points \( Z_4 \) and \( Z_5 \) must be both in \([Z_2, Z_3]\) or both in \( Z_2Z_3 \setminus [Z_2, Z_3] \).

### 11.8.2 Concurrency

Given non-collinear points \( Z_1, Z_2, Z_3 \), suppose now that for \( Z_4, Z_5 \in Z_2Z_3 \) the half-lines \([Z_1, Z_4], [Z_1, Z_5] \) are isogonal conjugates with respect to the angle-support \([Z_2Z_1Z_2] \), for \( Z_6, Z_7 \in Z_2Z_3 \) the half-lines \([Z_2, Z_6], [Z_2, Z_7] \) are isogonal conjugates with respect to the angle-support \([Z_3Z_2Z_1] \), and for \( Z_8, Z_9 \in Z_1Z_2 \) the half-lines \([Z_3, Z_8], [Z_3, Z_9] \) are isogonal conjugates with respect to the angle-support \([Z_1Z_2Z_3] \). Then by 11.8.1, with an obvious notation we have \( \lambda_4 \lambda_5 \mu_6 \mu_7 v_8 v_9 = \frac{|Z_1Z_2|^2 |Z_2Z_3|^2 |Z_3Z_1|^2}{|Z_3Z_1|^2 |Z_1Z_2|^2 |Z_2Z_3|^2} = 1 \).

Now if \( Z_1Z_4, Z_3Z_6, Z_3Z_8 \) are concurrent, by Ceva’s theorem we have \( \lambda_4 \mu_6 v_8 = 1 \). It follows that \( \lambda_5 \mu_7 v_9 = 1 \), which is the condition (11.5.1) for \( Z_1Z_5, Z_2Z_7, Z_3Z_9 \). Then if two of these are concurrent, the third must pass through their point of intersection.

### 11.8.3 Symmedians

If in 11.8.2 \([Z_1, Z_4], [Z_2, Z_6], [Z_3, Z_8] \) are the median half-lines of \([Z_1, Z_2, Z_3] \), then their isogonal conjugates \([Z_1, Z_5], [Z_2, Z_7], [Z_5, Z_9] \) are called the **symmedians** of the triangle. Now the mid-points \( Z_4, Z_6, Z_8 \) lie in the segments \([Z_2, Z_3], [Z_3, Z_1], [Z_1, Z_2] \), respectively. Hence the points \( Z_5, Z_7, Z_9 \) lie in the segments \([Z_2, Z_3], [Z_3, Z_1], [Z_1, Z_2] \), respectively. By the cross-bar theorem the symmedian lines \( Z_1Z_5, Z_2Z_7 \) must meet and then \( Z_5Z_9 \) must pass through their point of intersection. This point of concurrency is called the **symmedian point** of the triangle.

To identify the symmedians further, suppose that \( O \) be the centre of the circumcircle of the triangle \([Z_1, Z_2, Z_3] \), and \( W_1 \) the mid-point of \( \{Z_2, Z_3\} \). Let the line \( OW_1 \) meet the circumcircle, on the opposite side of \( Z_2Z_3 \) from \( Z_1 \), at the point \( U_1, [Z_1, W_1 \) meet the circle again at \( Z_4 \), and the line through \( Z_4 \) parallel to \( Z_2Z_3 \) meet the circle again at \( Z_4 \).

Then \( |Z_2Z_1Z_3| \) and \( |Z_4Z_1Z_5| \) have the same mid-line \( Z_1U_1 \) as each other. Thus \([Z_1, Z_5] \) is isogonal conjugate of the median half-line \([Z_1, Z_4] \) and so is the corresponding symmedian.

![Figure 11.22. Symmedians.](image-url)
Exercises

11.1 Show that if \( Z_1 \neq Z_2 \), the points \( Z \) on the perpendicular bisector of \([Z_1, Z_2]\) are those for which \( \overrightarrow{OZ} = \frac{1}{2}(\overrightarrow{OZ_1} + \overrightarrow{OZ_2}) + t(\overrightarrow{OZ_2} - \overrightarrow{OZ_1}) \perp \), for some \( t \in \mathbb{R} \).

11.2 If \( l = Z_1Z_2 \), then \( Z_4 = \pi_l(Z_3) \) if and only if \( Z_4 = Z_1 + s(Z_2 - Z_1) \) where

\[
s = \frac{(\overrightarrow{OZ_3} - \overrightarrow{OZ_1}) \cdot (\overrightarrow{OZ_2} - \overrightarrow{OZ_1})}{\| \overrightarrow{OZ_2} - \overrightarrow{OZ_1} \|^2},
\]

and also if and only if \( \overrightarrow{OZ_4} = \overrightarrow{OZ_3} + t(\overrightarrow{OZ_2} - \overrightarrow{OZ_1}) \perp \), where

\[
t = -\frac{(\overrightarrow{OZ_3} - \overrightarrow{OZ_1}) \cdot (\overrightarrow{OZ_2} - \overrightarrow{OZ_1}) \perp}{\| \overrightarrow{OZ_2} - \overrightarrow{OZ_1} \|^2}.
\]

11.3 If \( l = Z_1Z_2 \), then \( Z_4 = s_l(Z_3) \) if and only if \( \overrightarrow{OZ_4} = \overrightarrow{OZ_3} + t(\overrightarrow{OZ_2} - \overrightarrow{OZ_1}) \perp \), where

\[
t = -2\frac{(\overrightarrow{OZ_3} - \overrightarrow{OZ_1}) \cdot (\overrightarrow{OZ_2} - \overrightarrow{OZ_1}) \perp}{\| \overrightarrow{OZ_2} - \overrightarrow{OZ_1} \|^2}.
\]

11.4 If \( Z_2 \notin [Z_0, Z_1] \) and \( l \) is the mid-line of the angle support \([Z_1Z_0Z_2] \), then \( Z \in l \) if and only if

\[
\overrightarrow{OZ} = \overrightarrow{OZ_0} + t \left[ \frac{1}{\| \overrightarrow{OZ_2} - \overrightarrow{OZ_0} \|} (\overrightarrow{OZ_2} - \overrightarrow{OZ_0}) - \frac{1}{\| \overrightarrow{OZ_1} - \overrightarrow{OZ_0} \|} (\overrightarrow{OZ_1} - \overrightarrow{OZ_0}) \right] \perp,
\]

for some \( t \in \mathbb{R} \).

11.5 Prove that \( \overrightarrow{OZ} - \overrightarrow{OZ_1} = \cos \alpha(\overrightarrow{OZ} - \overrightarrow{OZ_1}) + \sin \alpha(\overrightarrow{OZ} - \overrightarrow{OZ_1}) \perp \), represents a rotation about the point \( Z_1 \), through the angle \( \alpha \).

11.6 For any vector \( \overrightarrow{OZ} \), with \( Z \equiv \mathbb{R} (x, y) \), define

\[
\overrightarrow{OZ}^\perp = \overrightarrow{OU}, \quad \overrightarrow{OZ}^\top = \overrightarrow{OV},
\]

where \( U \equiv \mathbb{R} (x, -y) \), \( V \equiv \mathbb{R} (y, x) \), so that \( U = s_{OJ}(Z) \), \( V = s_l(Z) \), \( l \) being the mid-line of \([IOJ]\). Prove that

(i) \[
(\overrightarrow{OZ_1} + \overrightarrow{OZ_2})^\perp = \overrightarrow{OZ_1}^\perp + \overrightarrow{OZ_2}^\perp,
\]

(ii) \[
(k\overrightarrow{OZ})^\perp = k(\overrightarrow{OZ})^\perp,
\]
(iii) \( (\overrightarrow{OZ})^\dagger = \overrightarrow{OZ} \),

(iv) \( (\overrightarrow{OZ_1} + \overrightarrow{OZ_2})^\dagger = \overrightarrow{OZ_1}^\dagger + \overrightarrow{OZ_2}^\dagger \),

(v) \( (k\overrightarrow{OZ})^\dagger = k(\overrightarrow{OZ})^\dagger \),

(vi) \( (\overrightarrow{OZ})^\dagger = \overrightarrow{OZ} \),

(vii) \( (\overrightarrow{OZ})^\dagger = \overrightarrow{OZ}^\perp \),

(viii) \( (\overrightarrow{OZ})^\dagger = -\overrightarrow{OZ}^\perp \).

Prove that axial symmetry in the line through the origin, with angle of inclination \( \alpha \), is given by \( \overrightarrow{OZ} = \cos 2\alpha \overrightarrow{OZ}^\perp + \sin 2\alpha \overrightarrow{OZ}^\parallel \).

11.7 For non-collinear points \( Z_1, Z_2, Z_3 \), suppose that

\[
\overrightarrow{OZ_4} = \overrightarrow{OZ_2} + (\overrightarrow{OZ_1} - \overrightarrow{OZ_2})^\perp, \quad \overrightarrow{OZ_5} = \overrightarrow{OZ_2} - (\overrightarrow{OZ_3} - \overrightarrow{OZ_2})^\perp.
\]

Show that then \( Z_1Z_5 \perp Z_3Z_4 \), and in fact

\[
\overrightarrow{OZ_5} - \overrightarrow{OZ_1} = (\overrightarrow{OZ_4} - \overrightarrow{OZ_3})^\perp.
\]

11.8 Prove that \( \delta_\mathcal{P}(Z_1, Z_2, Z_3) + \delta_\mathcal{P}(Z_1, Z_4, Z_3) = \delta_\mathcal{P}(Z_1, Z_5, Z_3) \), where \( (Z_1, Z_2) \uparrow (Z_4, Z_5) \).

11.9 If a point \( Z \) be taken on the circumcircle of an equilateral triangle \([Z_1, Z_2, Z_3]\), prove that when \( Z \) is on the opposite side of \( Z_2Z_3 \) from \( Z_1 \), \( |Z, Z_1| = |Z, Z_2| + |Z, Z_3| \).

11.10 For a triangle \([Z_1, Z_2, Z_3]\), if \( Z_4 \) is the foot of the perpendicular from \( Z_1 \) to \( Z_2Z_3 \), show that \( Z_4 \) is the mid-point of the orthocentre and the point where the line \( Z_1Z_4 \) meets the circumcircle again.

11.11 Deduce the Pasch property of a triangle from Menelaus’ theorem.

Trigonometric functions in calculus

COMMENT. In 3.7.1 and 9.3.1 we extended degree-measure to reflex angles, but the only use we have made of this hitherto has been for the purposes of notation in Chapter 9. In this chapter we relate it to the length of an arc of a circle, defining $\pi$ in the process. In doing this we make a start on calculus for the cosine and sine functions, introduce radian measure of angles and can go on to derive Maclaurin series. We also derive the area of a disk. In doing this we assume from the calculus definition of the length of a rectifiable curve, the Riemann integral and a formula for area in terms of a line integral; this is done so as to save labour, although it would be possible to handle arc-length of a circle and the area of a disk more elementarily.

12.1 REPEATED BISECTION OF AN ANGLE

12.1.1

Addition $\oplus$ is associative on $\mathfrak{A}^*(\mathfrak{F})$.

Proof. On using 9.3.2 instead of 9.3.3, as in the proof of 9.3.3(iii) we see that

$$\cos[(\alpha \oplus \beta) \oplus \gamma] = \cos[\alpha \oplus (\beta \oplus \gamma)],$$
$$\sin[(\alpha \oplus \beta) \oplus \gamma] = \sin[\alpha \oplus (\beta \oplus \gamma)].$$

Thus $(\alpha \oplus \beta) \oplus \gamma$ and $\alpha \oplus (\beta \oplus \gamma)$ are the angles in $\mathfrak{A}^*(\mathfrak{F})$ with the same cosine and the same sine, so they are the same angle except perhaps when $P_3 = Q$ and either angle could be $0_\mathfrak{F}$ or $360_\mathfrak{F}$. Thus $(\alpha \oplus \beta) \oplus \gamma = \alpha \oplus (\beta \oplus \gamma)$, except perhaps when either side is a null or full angle. But when each of $\alpha, \beta, \gamma$ is $0_\mathfrak{F}$, then each of $(\alpha \oplus \beta) \oplus \gamma$, $\alpha \oplus (\beta \oplus \gamma)$ is $0_\mathfrak{F}$ and so they are equal. If any of $\alpha, \beta, \gamma$ is non-null, and either of $(\alpha \oplus \beta) \oplus \gamma$, $\alpha \oplus (\beta \oplus \gamma)$ is $0_\mathfrak{F}$ or $360_\mathfrak{F}$ then both of them must be $360_\mathfrak{F}$, and again they are equal.
**Definition.** Given any angle \( \alpha \in \mathcal{A}^*(
abla) \), in 9.4.1 we defined \( \frac{1}{2} \alpha \). Now for any integer \( n \geq 1 \), \( \frac{1}{2^n} \alpha \) is defined inductively by

\[
\frac{1}{2^n} \alpha = \frac{1}{2} \alpha, \quad \text{and for all } \ n \geq 1, \quad \frac{1}{2^{n+1}} \alpha = \frac{1}{2} \left( \frac{1}{2^n} \alpha \right).
\]

For all \( \alpha \in \mathcal{A}^*(
abla) \), \( \frac{1}{2} |\alpha| = \frac{1}{2} |\alpha| \).

**Proof.** We use the notation of 9.4.1. From the definition of midl\( QOP \) this is immediate when \( P \in \mathcal{H}_1 \), so we suppose that \( P \in \mathcal{H}_2, P \neq S, P \neq Q \). Then

\[
|\alpha| = 180 + |\angle SOP| = |\angle QOP'| + |\angle P'OS| + |\angle SOP|
\]

\[
= |\angle QOP'| + |\angle P'OP| = 2|\angle QOP|
\]

by 3.7.1.

For this, note that \([P, P'] \) meets \( OQ \) in a point \( G \). If \( H = mp(Q, P) \), then \( P' \in OH \) and if \( \mathcal{H}_5, \mathcal{H}_6 \) are the closed half-planes with common edge \( OH \), with \( Q \in \mathcal{H}_5 \), then as \( H \in [Q, P] \) we have \( P \in \mathcal{H}_6 \). Then \([P', P] \subset \mathcal{H}_6 \) so \( G \in \mathcal{H}_6 \). But \([O, Q] \subset \mathcal{H}_5 \), \([O, S] \subset \mathcal{H}_6 \) so \( G \in [O, S] \). Thus \([O, S] \subset \mathcal{I} \mathcal{R}([P'OP]) \).

If \( \alpha, \beta \in \mathcal{A}^*(
abla) \) are such that \( |\alpha| + |\beta| \leq 360 \), then

\[
\frac{1}{2} (\alpha \oplus \beta) = \frac{1}{2} \alpha \oplus \frac{1}{2} \beta.
\]

**Proof.** By the commutativity and associativity of \( \oplus \),

\[
(\frac{1}{2} \alpha \oplus \frac{1}{2} \beta) \oplus (\frac{1}{2} \alpha \oplus \frac{1}{2} \beta)
\]

\[
= (\frac{1}{2} \alpha \oplus \frac{1}{2} \alpha) \oplus (\frac{1}{2} \beta \oplus \frac{1}{2} \beta)
\]

\[
= \alpha \oplus \beta,
\]

so we show that under the condition \( |\alpha| + |\beta| \leq 360 \), if \( \frac{1}{2} \alpha \oplus \frac{1}{2} \beta \) has support \( \overline{QOP} \), then \( P'_3 \in \mathcal{H}_1 \).

Let \([O, P'_1] = i(\alpha), [O, P'_2] = i(\beta) \) with \( |O, P'_1| = |O, P'_2| = |O, Q| = k \). Then \( \frac{1}{2} \alpha \) and \( \frac{1}{2} \beta \) are the angles in \( \mathcal{A}^*_{\nabla} \) with supports \( \overline{QOP}'_1, \overline{QOP}'_2 \), respectively.
Without loss of generality we suppose that \(|\alpha| \leq |\beta|\), so that by the above, \(|\frac{1}{2} \alpha| \leq |\frac{1}{2} \beta|\). As \(|\frac{1}{2} \alpha| + |\frac{1}{2} \beta| \leq 180\), then \(|\frac{1}{2} \alpha| \leq 90, |\frac{1}{2} \beta| \leq 180\), so that \(P_2 \in \mathcal{H}_1, P'_2 \in \mathcal{H}_1\) and \([O,P'_2] \subset \mathcal{R}(QOP'_2)\). Let the angle in \(\mathcal{A}^* (\mathcal{F})\) with degree measure \(\frac{1}{2}(|\alpha| + |\beta|)\) have support \(\overrightarrow{QON}\) where \(|O,N| = k\). Then as \(\frac{1}{2}(|\alpha| + |\beta|) \leq 180\) we have \(N \in \mathcal{H}_1\).

Let the angle in \(\mathcal{A}^* (\mathcal{F})\) with degree measure \(\frac{1}{4}(|\alpha| + |\beta|)\) have support \(\overrightarrow{QOW}\), where \(|O, W| = k\). Then \(W \in \mathcal{H}_1\) and \([O,P'_2] \subset \mathcal{R}(QOW)\) as \(\frac{1}{2}|\alpha| \leq \frac{1}{4}(|\alpha| + |\beta|)\). Thus
\[
\angle P'_1 OW = \angle QOW - \angle QOP'_1 = \frac{1}{4}(|\alpha| + |\beta|) - \frac{1}{2}|\alpha| = \frac{1}{4}(|\beta| - |\alpha|).
\]
As \(\frac{1}{4}(|\alpha| + |\beta|) \leq \frac{1}{2}|\beta|\) we have \([O, W] \subset \mathcal{R}(QOP'_2)\). Then
\[
\angle WOP'_2 = \angle QOP'_2 - \angle QOW = \frac{1}{2}|\beta| - \frac{1}{4}(|\alpha| + |\beta|) = \frac{1}{4}(|\beta| - |\alpha|).
\]
As \(\angle P'_1 OW = \angle WOP'_2\) we have \(OW = \text{midl}P'_1 OP'_2\).

By a similar argument
\[
\angle QOW = \frac{1}{4}(|\alpha| + |\beta|) = \angle WNQ,
\]
so \(OW = \text{midl}QON\). Then \(N = s_{ow}(Q)\) and so \(\frac{1}{2} \alpha + \frac{1}{2} \beta\) has support \(\overrightarrow{QON}\).

When \(\frac{1}{2}(|\alpha| + |\beta|) < 180\) this gives that \(P'_3 = N\) and so \(\frac{1}{2} \alpha + \frac{1}{2} \beta = \frac{1}{2} (\alpha + \beta)\).
The remaining case is when \(|\alpha| + |\beta| = 360\). Then \(\frac{1}{2}(|\alpha| + |\beta|) = 180\) so \(\frac{1}{2} \alpha + \frac{1}{2} \beta = 180_{\mathcal{F}}\), while \(\alpha + \beta = 360_{\mathcal{F}}\) so \(\frac{1}{2} (\alpha + \beta) = 180_{\mathcal{F}}\).

**COROLLARY 1.** If \(\alpha, \beta \in \mathcal{A}^*(\mathcal{F})\) are such that \(|\alpha| + |\beta| \leq 360\), then for all integers \(n \geq 1\),
\[
\frac{1}{2^n} (\alpha + \beta) = \frac{1}{2^n} \alpha + \frac{1}{2^n} \beta.
\]

**COROLLARY 2.** If \(\alpha, \beta \in \mathcal{A}^*(\mathcal{F})\) are such that \(|\alpha| + |\beta| \leq 360\), then
\[
|\alpha + \beta| = |\alpha| + |\beta|.
\]

**Proof.** In the course of the proof we saw that, under the given conditions,
\[
\frac{1}{2} \alpha + \frac{1}{2} \beta = \frac{1}{2}(|\alpha| + |\beta|), \quad \frac{1}{2} \alpha + \frac{1}{2} \beta = \frac{1}{2} (\alpha + \beta).
\]
From these \(\frac{1}{2} (\alpha + \beta) = \frac{1}{2} (\alpha + \beta)\), so that \(|\alpha + \beta| = |\alpha| + |\beta|\).

## 12.2 Circular Functions

### 12.2.1 Definition.** Let \(x \in \mathbb{R}\) satisfy \(0 \leq x \leq 360\). Then if for \(\alpha \in \mathcal{A}^*(\mathcal{F})\) we have \(|\alpha| = x\),
we write \(c(x) = \cos \alpha, s(x) = \sin \alpha\). By 9.6, \(c\) and \(s\) do not depend on \(\mathcal{F}\).
The functions c and s have the following properties:-

(i) For $0 \leq x \leq 360, 0 \leq y \leq 360, x + y \leq 360$, 

$$c(x + y) = c(x)c(y) - s(x)s(y), \quad s(x + y) = s(x)c(y) + c(x)s(y).$$

(ii) For $0 \leq x \leq 360$, $c(x)^2 + s(x)^2 = 1$.

(iii) For $0 \leq x \leq 360$, $c(x) = 1 - 2s(\frac{1}{2}x)^2$, $s(x) = 2c(\frac{1}{2}x)s(\frac{1}{2}x)$.

**Proof.** These follow immediately from the definition of c and s, and the formulae for $\cos(\alpha + \beta)$ and $\sin(\alpha + \beta)$.

**Definition.** For $0 \leq x \leq 360$ and integers $n \geq 3$, let 

$$u_n(x) = 2^n s\left(\frac{x}{2^{n+1}}\right), \quad v_n(x) = 2^n s\left(\frac{x}{2^{n+1}}\right).$$

**COMMENT.** When $n \geq 1$, $u_n$ is the sum of the areas of $2^{n+1}$ non-overlapping congruent triangles, each having its vertex at the centre of the circle/arc with radius length 1, and each having the end-points of its base on the circle/arc.

![Figure 12.3](image1)

When $n \geq 1$, $v_n$ is the sum of the areas of $2^n$ non-overlapping congruent triangles, each having its vertex at the centre of the circle/arc, and each having its base-line a tangent to the circle/arc. Our reason for taking $n \geq 3$ is that then

$$\frac{x}{2^{n+1}} \leq \frac{360}{16} = 22.5 < 45.$$
Circular functions

The sequences \( u_n, v_n \) have the following properties:

(i) \((u_n)\) is non-decreasing.

(ii) \((v_n)\) is non-increasing.

(iii) For \(0 < x \leq 360\) and \(n \geq 2\), we have \(0 < u_n(x) \leq v_n(x)\).

(iv) As \(n \to \infty\), \(u_n(x)\) and \(v_n(x)\) tend to a common limit \(\mu(x)\) and

\[
\forall n, u_n(x) \leq \mu(x) \leq v_n(x).
\]

**Proof.**

(i) For

\[
u_n(x) = 2^{n+1} s \left( \frac{x}{2^{n+2}} \right) c\left( \frac{x}{2^{n+2}} \right) \leq u_{n+1}(x).
\]

(ii) For

\[
v_n(x) = \frac{2^{n+1} s \left( \frac{x}{2^{n+2}} \right) c\left( \frac{x}{2^{n+2}} \right)}{2c \left( \frac{x}{2^{n+2}} \right)^2 - 1} = v_{n+1}(x) c \left( \frac{x}{2^{n+2}} \right)^2 \to v_{n+1}(x)
\]

as \(c \left( \frac{x}{2^{n+2}} \right)^2 < 1\) and so \(2c \left( \frac{x}{2^{n+2}} \right)^2 - 1 < c \left( \frac{x}{2^{n+2}} \right)^2\), while \(c \left( \frac{x}{2^{n+2}} \right)^2 > 0\) and thus \(2c \left( \frac{x}{2^{n+2}} \right)^2 - 1 > 0\).

(iii) For

\[
u_n(x) = v_n(x) c\left( \frac{x}{2^{n+1}} \right) \leq v_n(x).
\]

(iv) By (i), (ii) and (iii), \(u_n(x) \leq v_3(x)\) so we have a non-decreasing sequence which is bounded above. Hence there is some \(\mu(x)\) such that \(\lim_{n \to \infty} u_n(x) = \mu(x)\). It follows that \(s \left( \frac{x}{2^{n+1}} \right) \to 0\ (n \to \infty)\) and hence

\[
c \left( \frac{x}{2^{n+1}} \right) = 1 - 2s \left( \frac{x}{2^{n+2}} \right)^2 \to 1\ (n \to \infty).
\]

But then

\[
v_n(x) u_n(x) = c \left( \frac{x}{2^{n+1}} \right)^{-1} \to 1\ (n \to \infty),
\]

and so as well \(\lim_{n \to \infty} v_n(x) = \mu(x)\). As \(u_n(x)\) is non-decreasing and \(v_n(x)\) is non-increasing we must have \(u_n(x) \leq \mu(x) \leq v_n(x)\).

For \(x \geq 0, y \geq 0, x + y \leq 360\),

\[
\mu(x + y) = \mu(x) + \mu(y).
\]

**Proof.** For

\[
u_n(x + y) = 2^n s \left( \frac{x + y}{2^{n+1}} \right) = 2^n s \left( \frac{x}{2^{n+1}} + \frac{y}{2^{n+1}} \right)
\]

\[
= 2^n s \left( \frac{x}{2^{n+1}} \right) \frac{y}{2^{n+1}} + c \left( \frac{x}{2^{n+1}} \right) 2^n s \left( \frac{y}{2^{n+1}} \right)
\]

\[
\to \mu(x) \cdot 1 + 1, \mu(y)\ (n \to \infty).
\]
COMMENT. This equation for \( \mu \) is referred to as Darboux’s functional equation.

There is a number \( p > 0 \) such that for \( 0 \leq x \leq 360 \), \( \mu(x) = px \).

**Proof.** We start by writing out a well known proof that any function \( \mu \) which satisfies Darboux’s functional equation on \([0,360]\) satisfies \( \mu(r) = r \mu(1) \) for all rational numbers \( r \) in \([0,360]\). On first taking \( y = x \) we have \( \mu(2x) = 2\mu(x) \); then taking \( y = 2x \), we get \( \mu(3x) = 3\mu(x) \); next taking \( y = 3x \), we get \( \mu(4x) = 4\mu(x) \); and proceeding this way we evidently get

\[
\mu(nx) = n\mu(x) \text{ for all } n \in \mathbb{N} \text{ and } 0 \leq x \leq \frac{360}{n}.
\]

This can be confirmed by induction on \( n \).

On applying this with \( n = m, x = 1/m \) for any \( m \in \mathbb{N} \) we deduce that

\[
\mu(1) = m\mu\left(\frac{1}{m}\right)
\]

so that

\[
\mu\left(\frac{1}{m}\right) = \frac{1}{m}\mu(1).
\]

Now on taking \( n \) and \( x = 1/m \) we see that

\[
\mu\left(\frac{n}{m}\right) = \mu\left(n\cdot\frac{1}{m}\right) = n\mu\left(\frac{1}{m}\right) = n\cdot\frac{1}{m}\mu(1) = \frac{n}{m}\mu(1).
\]

Thus \( \mu(r) = r\mu(1) \) for every rational number \( r \) with \( 0 < r \leq 360 \), and this extends to the case \( r = 0 \) also as putting \( x = y = 0 \) in Darboux’s functional equation gives \( \mu(0) = 0 \).

It remains to show that \( \mu(y) = y\mu(1) \) for each irrational number \( y \) with \( 0 < y < 360 \). Choose a decreasing sequence of rational numbers \( t_n(y) \) which converge to \( y \). By the case for rational numbers, we have \( \mu(t_n) = t_n\mu(1) \). Now \( t_n = (t_n - y) + y \) so by Darboux’s functional equation

\[
\mu(t_n) = \mu(t_n - y) + \mu(y),
\]

and so

\[
\mu(y) = t_n\mu(1) - \mu(t_n - y).
\]

We wish to make \( n \to \infty \) in this and take limits.

Now as defined \( \mu(z) > 0 \) for \( 0 < z < 360 \). Then if \( 0 < x < y < 360 \) as \( \mu(x) + \mu(y-x) = \mu(y) \) and \( \mu(y-x) > 0 \), we must have \( \mu(x) < \mu(y) \). Thus \( \mu \) is an increasing function. Hence as \( z \) decreases to \( 0 \), \( \mu(z) \) decreases and is positive and so the one-sided limit

\[
l = \lim_{z \to 0^+} \mu(z) = \lim_{z \to 0^+, z > 0} \mu(z).
\]
must exist. But the formula \(\mu(\frac{1}{n}) = \frac{\mu(1)}{n}\) shows that \(\mu(\frac{1}{n}) \to 0 (n \to \infty)\) and so we must have \(l = 0\). As \(t_n - y \to 0\) it follows that \(\mu(t_n - y) \to 0 (n \to \infty)\) and then

\[
\lim_{n \to \infty} \mu(y) = \lim_{n \to \infty} [t_n \mu(1)] + \lim_{n \to \infty} \mu(t_n - y)
\]

yields \(\mu(y) = y\mu(1) + 0\).

To conclude we take \(p = \mu(1)\) and note that this is positive as shown above.

12.2.2 Definition of \(\pi\)

**Definition.** We denote \(\mu(360)\) by \(\pi\). Then \(360p = \pi\) so that \(p = \frac{\pi}{360}\) and so

\[\mu(x) = \frac{\pi}{360}x.\]

### 12.3 DERIVATIVES OF COSINE AND SINE FUNCTIONS

12.3.1

With the notation of 12.1,

\[
\lim_{t \to 0^+} \frac{s(t)}{t} = \frac{\pi}{180}.
\]

**Proof.** We have seen above that for \(0 < x \leq 360\), taking \(n = 2\) in 12.2.1(iv),

\[0 < s\left(\frac{x}{8}\right) \leq \frac{\pi}{180} \frac{x}{8} \leq \frac{s\left(\frac{x}{8}\right)}{c\left(\frac{x}{8}\right)},\]

and so for \(0 < t < 45\),

\[0 < s(t) \leq \frac{\pi}{180} t \leq \frac{s(t)}{c(t)}.\]

From the first two inequalities here we infer that \(s(t) \to 0 (t \to 0^+)\) and hence

\[c(t) = 1 - 2s\left(\frac{t}{2}\right)^2 \to 1 (t \to 0^+).\]

As

\[\frac{\pi}{180} c(t) \leq \frac{s(t)}{t} \leq \frac{\pi}{180},\]

the result follows.

*For* \(0 < x < 360\) *the derivatives* \(c'(x)\) *and* \(s'(x)\) *exist and are given by*

\[c'(x) = -\frac{\pi}{180} s(x), \ s'(x) = \frac{\pi}{180} c(x).\]
Proof. Suppose that \(0 < x < 360\), and \(h > 0\) is so small that \(x + h < 360\), \(x - h > 0\). Then
\[
\frac{c(x + h) - c(x)}{h} = \frac{c(x)c(h) - s(x)s(h) - c(x)}{h} = c(x) \frac{c(h) - 1}{h} - s(x) \frac{s(h)}{h}.
\]
But \(c(h) - 1 = -2s(h) \frac{h}{2} \to 0 (h \to 0^+)\) and so
\[
\frac{c(x + h) - c(x)}{h} \to -\frac{\pi}{180} s(x) (h \to 0^+).
\]
Also
\[
c(x) = c(x - h) = c(x - h)c(h) + s(x - h)s(h),
\]
\[
s(x) = s(x - h) = c(x - h)s(h) + s(x - h)c(h).
\]
As \(c(h)^2 + s(h)^2 = 1\) we can solve these equations by Cramer’s rule to obtain
\[
c(x - h) = c(x)c(h) + s(x)s(h), \quad s(x - h) = s(x)c(h) - c(x)s(h).
\]
From the first of these, by a similar argument to that above, it follows that
\[
\frac{c(x - h) - c(x)}{-h} \to -\frac{\pi}{180} s(x) (h \to 0^+).
\]
These results combined show that \(c'(x) = -\frac{\pi}{180} s(x)\).

The other result is proved similarly.

12.4 PARAMETRIC EQUATIONS FOR A CIRCLE

12.4.1 Area of a disk

The disk \(D(O;k) = \{ Z : |O,Z| \leq k \}\) has area \(\pi k^2\).

Proof. We use a well-known expression for area as the value of a line integral; see e.g. Apostol [1, Volume II, page 383].

If \(\gamma\) is the path with equation \(x = kc(t), y = ks(t) (0 \leq t \leq 360)\), then \(\gamma\) traverses the circle \(C(O,k)\) once. Moreover if \(O \equiv (0,0), P \equiv (kc(t),ks(t)), T \equiv (kc'(t),ks'(t)) = (-\frac{\pi ks(t)}{180}, \frac{\pi kc(t)}{180})\), we have that
\[
\delta_{\gamma}(O,P,T) = \frac{\pi}{360} k^2 [c^2(t) + s^2(t)] = \frac{\pi}{360} k^2 > 0.
\]
Now \(C(O;k)\) is the boundary of \(D(O;k)\) and so the area of \(D(O;k)\) is given by
\[
\frac{1}{2} \int_{\gamma} xdy - ydx = \frac{1}{2} \int_{0}^{360} k^2 [c(t)s'(t) - s(t)c'(t)] dt
\]
\[
= \frac{1}{2} \int_{0}^{360} \frac{\pi}{180} k^2 dt = \pi k^2.
\]
Sec. 12.4

Parametric equations for a circle

12.4.2 Length of an arc of a circle

For $P \in \mathcal{C}(O;k)$ let $\alpha$ be an angle in $\mathcal{A}^\circ(\mathcal{F})$ with support $|QOP|$. Let $|\alpha| = \theta$ and $\gamma$ be the curve with parametric equations $x = kc(t)$, $y = ks(t)$ ($0 \leq t \leq \theta$). Then $\gamma$ has the end-points $Q$ and $P$ and has length $\frac{\pi}{180} \theta k$.

**Proof.** The length of $\gamma$ is given by

$$\int_0^\theta \sqrt{[kc'(t)]^2 + [ks'(t)]^2} \, dt = \frac{\pi}{180} \theta k.$$

**NOTE.** In the foregoing result, when $\theta = 360$, $\gamma$ is the circle $\mathcal{C}(O;k)$ and has length $2\pi k$. When $\theta = 180$, $\gamma$ is a semi-circle and has length $\pi k$. For other cases, we note that the line $QP$ has equation

$$s(\theta)(x-k) - [c(\theta) - 1]y = 0.$$

The left-hand side in this has the value $-ks(\theta)$ when $x = y = 0$, and when $x = kc(t)$, $y = ks(t)$ the value

$$k\{s(\theta)[c(t)-1] - [c(\theta) - 1]s(t)\} = k[-2s(\theta)s^2(\frac{1}{2}t) + 2s^2(\frac{1}{2}\theta)s(t)]$$

$$= 4ks(\frac{1}{2}\theta)s(\frac{1}{2}t)\left[s(\frac{1}{2}\theta)c(\frac{1}{2}t) - s(\frac{1}{2}t)c(\frac{1}{2}\theta)\right]$$

$$= 4ks(\frac{1}{2}\theta)s(\frac{1}{2}t)s(\frac{1}{2}\theta - \frac{1}{2}t)$$

$$> 0,$$

for $0 < t < \theta$.

When $\theta < 180$, we have $-s(\theta) < 0$ so that $Z \equiv (kc(t), ks(t))$ is in the closed half-plane $\mathcal{H}_6$ with edge $QP$ which does not contain $O$. Thus, recalling 7.5, $\gamma$ is the minor arc with end-points $Q$ and $P$.

When $180 < \theta < 360$, $-s(\theta) > 0$ so $Z$ is in the closed half-plane $\mathcal{H}_5$ with edge $QP$ which contains $O$. Thus $\gamma$ is the major arc with end-points $Q$ and $P$.

12.4.3 Radian measure

**Definition.** If, for any angle $\alpha$, $x = |\alpha|$ then $\frac{\pi}{180}x$ is called the **radian measure** of $\alpha$, and denoted by $|\alpha|^r$. We also define, for $0 \leq x \leq 2\pi$,

$$C(x) = c\left(\frac{180}{\pi}x\right), \quad S(x) = s\left(\frac{180}{\pi}x\right),$$

and then by the chain rule have

$$C'(x) = -S'(x), \quad S'(x) = C(x),$$

for $0 < x < 2\pi$. 
12.5 EXTENSION OF DOMAINS OF COSINE AND SINE

12.5.1

NOTE. If we define \( E(x) \) by \( E(x) = C(x) + iS(x) \) \((0 \leq x \leq 2\pi)\), where \( i^2 = -1 \), then by 12.2.1(i)

\[
E(x + y) = E(x)E(y) \quad (0 \leq x \leq 2\pi),
\]

and by 12.4.3

\[
E'(x) = iE(x) \quad (0 < x < 2\pi).
\]

It is natural to enquire if the definition of \( E \) can be extended from \([0, 2\pi]\) in such a way as to preserve its basic properties.

From (12.5.1) we note that in particular

\[
E(x + \pi) = -E(x) \quad (0 \leq x \leq \pi),
\]

as \( E(\pi) = -1 \), and if we specify that this is to hold for all \( x \in \mathbb{R} \) then the domain of definition of \( E \) becomes extended to \( \mathbb{R} \).

It follows that \( E(x + 2\pi) = E(x) \) for all \( x \in \mathbb{R} \) and so for all \( n \in \mathbb{Z} \), \( E(x + 2n\pi) = E(x) \). By the chain rule, for \( 0 < x < 2\pi \),

\[
E'(x + 2n\pi) = E'(x) = iE(x) = iE(x + 2n\pi).
\]

Thus for each \( n \in \mathbb{Z} \), \( E'(x) \) exists and satisfies \( E'(x) = iE(x) \) for \( 2n\pi < x < (2n + 2)\pi \).

Moreover for \( 0 < h < 2\pi \),

\[
\frac{E(2n\pi + h) - E(2n\pi)}{h} = \frac{E(h) - 1}{h} = \frac{C(h) - 1}{h} + \frac{iS(h)}{h} \rightarrow i \quad (h \rightarrow 0),
\]

while for \(-2\pi < h < 0\),

\[
\frac{E(2n\pi + h) - E(2n\pi)}{h} = \frac{E(2\pi + h) - 1}{h} = \frac{-E(\pi + h) - 1}{h} = \frac{-E(\pi + h) - E(\pi)}{h} \rightarrow -E'(\pi) \quad (h \rightarrow 0)
\]

Thus \( E'(2n\pi) \) exists for each \( n \in \mathbb{Z} \) and as its value there is \( i = iE(2n\pi) \), we see that \( E'(x) = iE(x) \) for all \( x \in \mathbb{R} \).

We note that \(|E(x)| = \sqrt{C(x)^2 + S(x)^2} = 1\) for \( 0 \leq x \leq 2\pi \) and then as \( E \) has period \( 2\pi \), \(|E(x)| = 1\) for all \( x \). Hence \( E(x) \neq 0 \) for all \( x \in \mathbb{R} \).

Then for any fixed \( y \in \mathbb{R} \),

\[
\frac{d}{dx} \frac{E(x + y)}{E(x)} = \frac{E(x)iE(x + y) - E(x + y)iE(x)}{E(x)^2} = 0,
\]
so for some complex constant $c$,

$$E(x + y) = cE(x), \text{ for all } x \in \mathbb{R}.$$ 

On putting $x = 0$ we see that $c = E(y)$ and so $E(x + y) = E(x)E(y)$ for all $x, y \in \mathbb{R}$.

From $E'(x) = iE(x) \forall x \in \mathbb{R}$, we deduce that $C'(x) = -S(x), S'(x) = C(x), \forall x \in \mathbb{R}$. From these the usual Maclaurin series for $C(x)$ and $S(x)$ (or $E(x)$) can be derived and tables of approximations to them prepared; see e.g. Apostol [1, Volume I, pages 435–436]. By introducing arctan, $\pi$ could be expressed as the sum of infinite series and these used to prepare approximations efficiently; see e.g. Apostol [1, Volume I, pages 253–255, 284–285].

### 12.5.2

Given a frame of reference $\mathcal{F}$, let $Q \equiv (1, 0)$ and consider the points $Z$ of the unit circle $C(O; 1)$ and the angles $\theta = \angle_{\mathcal{F}} QOZ$ in $\mathcal{A}(\mathcal{F})$. If $s = |\theta|$ then $Z \sim \text{cis} \theta = C(s) + is(s)$. Any number $t \in \mathbb{R}$ such that

$$C(t) + iS(t) = C(s) + is(s)$$

is called a radian measure of $\theta$; collectively we shall call them the **multiple radian measures** of $\theta$. They have the form $t = s + 2n\pi$ where $n \in \mathbb{Z}$. We write $t \sim \angle_{\mathcal{F}} QOZ$.

Suppose now that $t_1 \sim \angle_{\mathcal{F}} QOZ_1 = \theta_1$ and $t_2 \sim \angle_{\mathcal{F}} QOZ_2 = \theta_2$. Then

$$E(t_1) = C(t_1) + iS(t_1) = \cos \theta_1 + i\sin \theta_1,$$

$$E(t_2) = C(t_2) + iS(t_2) = \cos \theta_2 + i\sin \theta_2,$$

and from this by multiplication we have that

$$E(t_1 + t_2) = E(t_1)E(t_2) = \cos(\theta_1 + \theta_2) + i\sin(\theta_1 + \theta_2).$$

Thus $t_1 + t_2 \sim \angle_{\mathcal{F}} QOZ_1 + \angle_{\mathcal{F}} QOZ_2$ and so addition of multiple measures corresponds to addition of angles.

Given any $t \in \mathbb{R}$, then $\gamma(u) = E(ut) \ (0 \leq u \leq 1)$ gives a curve on the unit circle, with initial point $Q$ and terminal point $Z$. If $t \not\in [-2\pi, 2\pi]$ then $\gamma$ winds around the origin and the curves generated in this way give us some pictorial feel for these multiple radian measures of angles.
This page intentionally left blank
List of axioms

AXIOM A₁. Each line is a proper non-empty subset of Π. For each set \{A, B\} of two distinct points in Π, there is a unique line in Λ to which A and B both belong.

AXIOM A₂. Each natural order \(\leq\) has the properties:
(i) \(A \leq_{l} A\) for all points \(A \in l\);
(ii) if \(A \leq_{l} B\) and \(B \leq_{l} C\) then \(A \leq_{l} C\);
(iii) if \(A \leq_{l} B\) and \(B \leq_{l} A\), then \(A = B\);
(iv) for any points \(A, B \in l\), either \(A \leq_{l} B\) or \(B \leq_{l} A\).

AXIOM A₃. Open half-planes \(G_1, G_2\) with common edge \(l\) have the properties:
(i) \(\Pi \setminus l = G_1 \cup G_2\);
(ii) \(G_1\) and \(G_2\) are both convex sets;
(iii) if \(P \in G_1\) and \(Q \in G_2\), then \([P, Q] \cap l \neq \emptyset\).

AXIOM A₄. Distance has the following properties:
(i) \(|A, B| \geq 0\) for all \(A, B \in \Pi\);
(ii) \(|A, B| = |B, A|\) for all \(A, B \in \Pi\);
(iii) if \(Q \in [P, R]\), then \(|P, Q| + |Q, R| = |P, R|\);
(iv) given any \(k \geq 0\) in \(R\), any line \(l \in \Lambda\), any point \(A \in l\) and either natural order \(\leq_{l}\) on \(l\), there is a unique point \(B \in l\) such that \(A \leq_{l} B\) and \(|A, B| = k\), and a unique point \(C \in l\) such that \(C \leq_{l} A\) and \(|A, C| = k\).

AXIOM A₅. Degree-measure \(|\alpha|\) of angles has the following properties:
(i) In all cases \(|\alpha| \geq 0\);
(ii) if \(\alpha\) is a straight-angle, then \(|\alpha| = 180\);
(iii) if \( \angle BAC \) is a wedge-angle and the point \( D \neq A \) lies in the interior region \( \mathcal{R}(\{BAC\}) \), then

\[
|\angle BAD|^{\circ} + |\angle DAC|^{\circ} = |\angle BAC|^{\circ},
\]

while if \( \{BAC\} \) is a straight angle-support and \( D \not\in AB \), then

\[
|\angle BAD|^{\circ} + |\angle DAC|^{\circ} = 180;
\]

(iv) if \( B \neq A \), if \( \mathcal{H}_1 \) is a closed half-plane with edge \( AB \), and if the half-lines \([A,C] \) and \([A,D] \) in \( \mathcal{H}_1 \) are such that \( |\angle BAC|^{\circ} = |\angle BAD|^{\circ} \), then \([A,D] = [A,C] \);

(v) if \( B \neq A \), if \( \mathcal{H}_1 \) is a closed half-plane with edge \( AB \), and if \( 0 < k < 180 \), then there is a half-line \([A,C] \) in \( \mathcal{H}_1 \) such that \( |\angle BAC|^{\circ} = k \).

AXIOM A6. If triangles \( T \) and \( T' \), with vertices \( \{A,B,C\} \) and \( \{A',B',C'\} \), respectively, are such that

\[
|C,A| = |C',A'|, \quad |A,B| = |A',B'|, \quad |\angle BAC|^{\circ} = |\angle B'A'C'|^{\circ},
\]

then \( T \xrightarrow{(A,B,C)} T' \).

AXIOM A7. Given any line \( l \in \Lambda \) and any point \( P \not\in l \), there is at most one line \( m \) such that \( P \in m \) and \( l \parallel m \).

GEOMETRY with TRIGONOMETRY

Patrick D. Barry

This is a second course on Plane Euclidean Geometry, second in the sense that it is aimed at University students and deals with many of the geometrical concepts that they encountered less thoroughly at school. It is based on two main sources, first Euclid’s ‘The Elements’ in ancient Greece, and secondly on a modification of the ground-breaking approach in 1932 of G.D. Birkhoff, which assumed in advance a knowledge of the real number system and the ordinary algebra based on it. This approach allows for some strong axioms and makes for quite an efficient treatment. The aim is to be unobtrusively rigorous and to give complete proofs.

Chapter 1 deals with preliminaries: notes on history, deductive reasoning, details of Euclid’s ‘The Elements’, revision of geometrical concepts (amply supplied with figures), and prerequisites from other parts of mathematics.

Chapters 2 to 5 deal with synthetic (i.e. pure) geometry, with traditional results proved in a non-traditional logical system, going as far as Pythagoras’ theorem and area of convex polygons.

In Chapter 6, we introduce coordinate geometry via rectangular Cartesian coordinates. Many results on lines are proved there. The only use we make of angles there is to deal with perpendicularity of lines.

Chapter 7 is devoted to basic properties of circles, proved either with synthetic methods or coordinate methods. Sensed distances are introduced.

Chapter 8 is short. It deals with translations, axial symmetries, and (more generally) isometries.

Chapter 9 contains an original treatment of trigonometry, including cosine and sine of an angle, polar coordinates, addition and modified addition of angles, addition formulae, subtraction of angles, and the cosine and sine rules.

Chapter 10 introduces complex coordinates, sensed angles, rotations, orientation of a triple of non-collinear points, sensed area, applications to circles, duo-angles (angles between lines).

Chapter 11 deals with various methods of introducing coordinates other than the Cartesian coordinates of Chapter 6. First, there is the use of position vectors and areal coordinates, proving well-known theorems. Then there is an original section introducing ‘Mobile Coordinates’, emphasizing results for triangles.

Chapter 12 deals with the cosine and sine functions in calculus, and radian measure.
